factory than one in which the numbering device is concealed from view in the camera itself, and the new system permits of this being done by the interposition of a stencilled number on cardboard in front of the plate. The numbered ticket is slipped in grooves, and brought into register by the act of withdrawing the dark-slide shutter, the numerical series being recorded on the plate without the attention of the operator. The finishing touch to the device is given by a special accessory to the "Aptus" printing-frame in which only the first of a series of negatives has the number pressed upon it if so desired. Full illustrated particulars of these other midget apparatus are supplied in a special booklet issued by Messrs. Sharp and Hitchmough.

## News and Notes.

THE manager of the Bank of Italy and several other members of the Milan Alpine Club, one of whom had taken photographs of a part of the Riecco Valley, have been arrested by Austrian gendarmes and imprisoned at Caporetto, on Austrian territory. THE Royal Photographic Society. The programme of forthcoming meetings of the R.P.S. includes a number of fixtures in which colour photography figures largely. Next Tuesday, April 3rd, the Autochrome Company will give a practical demonstration of three-colour printing by their trichrome tissues, the *modus operandi* of which, it will be remembered, was described in our issue of February 9 last. ON April 10 the paper is on "A new method of calculating the results of development at various temperatures," by W. B. Ferguson, F.R.P.S. On April 24, Mr. W. A. Scoble, A.R.C.S., will read a paper on "The Red Sensitiveness of Dyed Films." A. Norman, on May 1, is to demonstrate "Three-colour photography by the Sanger-Shepherd Process," and the remaining papers up to May 22nd are to be filled by a paper by Major-General Terhouse, by Mr. F. Dunsterville, F.R.P.S., on "Bypaths in photography," and by S. E. Sheppard and C. E. K. Mills on "The Theory of Development and Combined Development and Fixation." C. E. KENNETH MEES, B.Sc., who is well known for his numerous papers on photo chemistry and sensitometry embodying results of investigations made alone or in collaboration with Mr. S. E. Sheppard, B.Sc., has joined the firm of Wratten and Wainwright, Croydon. We understand that his association with this established firm of plate-makers is based on a part-proprietary interest in the business. One of the first effects of Mr. Mees' con-

nection is the issue of two new colour-sensitive plates, a review of which we publish in another column.

THE R.P.S. House Exhibitions. As we mentioned last week, the present Coburn collection of landscapes and portraiture closes to-morrow, Saturday. Its successor at Russell Square is to be a collective exhibit of work by the Birmingham Photographic Society. If any provincial society can make a strong show it is Birmingham, for there is none which numbers in its own ranks so many exhibitors of standing. The names of Greathatch, Cruwys, Richards, Harold Baker, Smedley Aston, W. A. Clark, Bernard Moore, and Miss Silverston, not to mention the prolific Mrs. Barton, readily occur. It should be an easy matter to put on a fine show at Russell Square.

ONE of the earliest workers in dry plate manufacture passed away on Saturday, March 24th, in the person of M. Dominique Tackles. M. Tackles, who had arrived at the ripe age of 76, was the brother-in-law of Van Monckhoven, and was associated with him in the establishment of his dry plate works at Ghent. After Van Monckhoven's death, he directed the manufacture for the widow and family. He was a great lover of the carbon process, and he also reproduced several of the famous pictures in the Ghent picture gallery. An ardent sportsman, one of the pioneers of the Royal Sailing Club, and of very unassuming manners, and withal a genial companion, he was highly esteemed, and will be much regretted in the town where a great part of his life was spent.

THE Clevedon Photographic Society are holding an exhibition on May 15, 16, and 17. The Rev. F. C. Lambert, M.A., will act as judge, and the honorary secretary, from whom further particulars may be had, is Rev. E. A. Sandford, 18, Hallam Road, Clevedon.

THE Photographic Convention.—The first outward and visible sign of the *entente cordiale* which is to prevail at the Southampton meeting of the Convention in July reaches us in the shape of the French edition of the programme. We hope to see a large foreign contingent at the Convention.

A POSTCARD of metric equivalents in English measures is kindly sent us by our contributor, Mr. Charles Louis Hett, of Springfield, Brigg, whose advocacy of the metric system is additionally interesting from the fact that Mr. Hett is an engineer, and engaged in industrial operations on a considerable scale.

## Commercial & Legal Intelligence.

KENT AND LACY, Ltd. (Photographers, Newcastle-on-Tyne).—Debutante, dated 6th March, 1906, to secure £100, charged on the company's undertaking and property, present and future, including uncalled capital, has been registered. Holder—F. G. Lundy, 15, Grey-street, Newcastle-on-Tyne.

COPYRIGHT Action by Mr. Gambier Bolton.—Before the Chancery Division last week a motion was brought by Mr. Gambier Bolton, the author and owner of twelve photographs of animals and birds of which he had registered the copyright under the Fine Arts Copyright Act, 1862, for an injunction restraining the defendant, until the trial or further order, from copying or reproducing or importing into the United Kingdom, or publishing, selling, or offering for sale any copy or reproduction of the said photographs, or otherwise infringing the plaintiff's copyright therein. According to the "Times" report, the alleged infringement was committed by means of picture postcards printed by Theodore Eismann, of Leipzig, and which reproduced in whole or in part the subjects of the plaintiff's photographs. The defendant in his affidavits swore that until this action commenced he was ignorant of any infringement, and that he had done nothing beyond forwarding a parcel containing the postcards to a firm which he alleged had bought them direct from Eismann. He also said that Eismann believed himself to have acquired the right of reproduction in 1904 from M. Peiser, of Amsterdam, who professed to be the owner of it, and that on the issue of the writ he (the defendant) first became aware of any piracy and immediately communicated both with Eismann and the purchasing firm with the view of putting a stop to the distribution and to any further importation. The result of his action, he said, was that only a few of the postcards had been sold. He was willing to agree to a perpetual injunction, but submitted that he ought not, under the circumstances, to be ordered to pay all the costs. It was agreed to treat

the hearing as the trial of the action. Mr. Justice Swinfen Eady did not consider the evidence as wholly exculpating the defendant. He granted a perpetual injunction with costs and an inquiry as to damages, and made an order for delivery up of the infringing post-cards—being the full relief claimed in the action.

**THEFTS** from the Stereoscopic Company.—At the Clerkenwell Sessions last week, Wm. Stone and Fredk. Tyler were convicted of having smashed the windows of the London Stereoscopic and Photographic Company, Ltd., Regent Street, W., and stolen nine lockets and a pendant, value £26. Stone was sentenced to twenty-one months' hard labour and Tyler to three years' penal servitude and three years' police supervision.

**PHOTOGRAPHING a Band.**—On March 15 Mr. Charles Cornfield, bandmaster of the 7th Dragoon Guards, was sued by Mr. E. C. Elliott, trading as Elliott and Fry, photographers, of Baker Street, for £3 12s. for photographs supplied, and costs. The evidence showed that Messrs. Elliott and Fry wrote to the defendant asking to be allowed to photograph the regimental band, with which request he complied. An order for two photographs of the band, mounted, and twenty-two of the band on foot was put in. This was signed in defendant's name with his sanction. When the photographs arrived the men of the regiment refused to accept them. A second lot was sent, but Mr. Cornfield refused to have anything more to do with it. His Honour Judge Bacon gave judgment for the plaintiff, holding that the order was binding on the defendant.

## Correspondence.

\**\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\**\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### EMANATIONS FROM DARK SLIDES.

To the Editors.

Gentlemen,—Referring to the inquiry from O. E. Challis, re the "Emanations from Dark Slides," in the current issue, I beg to give this gentleman, and also other readers of your paper, the method used by ourselves when bringing new slides into use; it has always proved a certain cure.

Directly the new slides have been received from the maker they are opened out as wide as will allow them to stand on their edges, thus exposing the inside to the air, they are then placed on a shelf, or anywhere out of harm's way, where a current of air will circulate round them, but not in a position for the sun or damp to get at them. They are allowed to remain in this way until the peculiar smell, which is noticed upon opening a new slide, has entirely gone. This may perhaps take several days or weeks to accomplish. Should the slides be required for use during this airing process they should be carefully dusted before placing the plates in them, and after the exposed plates have been dealt with the slides must be opened out and placed back again on the shelf as before. It is advisable during this time to be careful to remove the plates from them as soon as possible after exposing; but when the smell has been eradicated no harm will come to the plates even if left in for a time.

Having had several lots of plates fogged in the same way as your correspondent through using new slides I hit upon this idea, and have never had the trouble occur since trying it. When once cured the slides may be put away, closed up in the ordinary way, without fear.

I am afraid using tinfoil as suggested would only cause further trouble by straining, and perhaps jamming the shutter of the slide when pulling it out or replacing.—Yours faithfully,

32, Burchell Road, Peckham, S.E.

H. E. EDMEADS.

March 23, 1906.

### MEASURING SHUTTER SPEEDS.

To the Editors.

Gentlemen,—As last summer I devised a pendulum method (not yet published) for determining the speeds of my shutters and time exposure bulbs, I was naturally interested in your "Ex Cathedra" notes (March 9) and Mr. Watkins' letter (March 23) on this subject.

I must confess that my procedure has not the alluring simplicity of the method described in Mr. Watkins' letter in "Photography"

(February 27), nor can I guarantee my results to the third decimal place of a second, which is a remarkably good performance for a pendulum with a nail suspension (i.e., for a pendulum of variable length). I do claim for my method, however, that the dynamical principles underlying it are sound, and that it is capable of giving results of as high a degree of accuracy as there is need for.

It is well known that for small angular swings the pendulum executes a simple harmonic motion, the characteristic of which is that the acceleration is varying continuously, always being in direct proportion to the distance of the centre of oscillation from the mid-point of swing.

In view of this continually varying acceleration I altogether fail to understand how Mr. Watkins can obtain by his method of procedure results which even distantly approach exactitude.

The differential equation expressing the time taken by a pendulum to move over a certain arc compared with the time of a complete swing does not, I believe, admit of an exact solution (i.e., it cannot be integrated without simplifying assumptions), and even the approximate solution demands an exact knowledge of the angles between the vertical and the axis of the pendulum at the extremities of the arc in order that the time taken to traverse the arc may be arrived at! The determination of these angles at the exact instants of the opening and closing of the shutter might well give one pause before committing one's self to such a method of shutter speed determination.

Mr. Watkins says, "That the position, to be exact," at which the exposures should be made in his procedure is when the pendulum is 17.79 of the distance between the starting point and the bottom of the swing. It is to be regretted that the reasoning on which this datum is founded has not been given. I believe it would be of considerable interest to students of dynamics.—Yours faithfully,

DOUGLAS CARNEGIE.

Blackheath, S.E.

To the Editors.

Gentlemen,—I have read Mr. Watkins' letter regarding his pendulum method of testing, but cannot understand why a system involving so many elaborate formulae and corrections should be chosen.

Most of us would be quite satisfied with an error of within 10 p.c. and spinning a bicycle wheel with a white cardboard disc fixed to the spokes will certainly within my experience give this degree of accuracy. For anyone who cares to try it, turn a bicycle upside down, fix a white card disc, about three inch diameter, to the spokes, so that the centre of disc is about nine inches from centre of wheel. Focus the camera on the wheel, getting the latter as large as possible on the plate, and get some one to spin the wheel at about 120 revolutions per minute for the maximum speed of shutter (assumed to be about 1/100th sec.), and proportionately slower will do for the lower speeds.

The resulting negative will show the disc elongated, the difference between the length and width being the movement during exposure. Using any convenient scale (a mm. measure is as good as any), the actual speed of shutter will be

$x$

$$R \times 6.28 \times r.$$

where

$x$  = movement of disc in mm.

$R$  = revolutions per second.

$r$  = radius of centre of disc in mm.

The accuracy of the method, of course, depends on the men spinning the wheel, but should not be more than 10 per cent. at the outside.

For focal plane shutters it is, of course, only necessary to test the speeds with maximum width of slit, the rest being inversely proportionate to the width of slit.—Yours truly,

73, Holly Avenue, Newcastle-on-Tyne.

March 24, 1906.

To the Editors.

Gentlemen,—Your editorial footnote following my letter in your issue of March 23 calls for some reply.

I was perfectly cognizant of the law as expressed by you concerning the speed of a pendulum, but perhaps I should have said near "the lowest point of the arc of movement," instead of *at the lowest point*, to have avoided the haggling over words. If I had not known that the exposures would show longer lines "the nearer they are made to the middle of the swing," I should not have made the remark

which seems to have raised the disdain of your critic. I am, however, obliged to him for the formula he gives for arriving at the correct value of the exposure when it is made at the centre of the swing. I venture to think, however, that there is either a mistake or a slip in the formula as given.

In a specific case I have recently taken, the length of the line of exposure of a shutter taken in the centre of the swing was 4.2 mm.; the length of the long line representing the one second was 93.9 mm.; the diameter of the sun 1.1 mm.; the angle of swing of the pendulum 15 degs., 15 minutes, 15 seconds; the length of the compound pendulum 933 mm.; and the length of a simple pendulum swinging to the same period would be 994 mm.

By the formula I gave, the actual exposure works out to 47.02, or as nearly as  $\frac{1}{47.02}$  of a second (= 0.0212). I see the formula would be better expressed if the figures were transposed, and I had stated it as  $\frac{S}{L} \times \frac{2}{\pi}$ . I own to a failing in not having done so.

By Dorman's scale the exposure measures about  $\frac{1}{47.5}$  or 0.021 of a second, and by Beck's system of shutter testing, said to be correct five per cent., the exposure is 0.022. All three are very nearly alike. I claim my method to determine the shutter speed more exactly than any other, but, if not so, it cannot be far from correct unless other methods are all wrong.

By the formula you have given I cannot arrive at figures within five per cent. of any of these values, perhaps by an error of my own. I would be glad, therefore, if you would kindly give the working out of the above case by your formula.

I note you still adhere to your contention that the bending of the flexible tube affects the vibration of the pendulum, and I am sorry I cannot understand my reasoning where I explain how this contention is reduced to an absurdity.—Your obedient servant,

Bala Lodge, Blackheath, S.E. ARTHUR A. WATKINS.  
March 26, 1906.

[As pointed out by a correspondent the pendulum moves harmonically—that is to say, the acceleration of the bob at a certain point varies directly as the distance from the lowest point. This

is expressed by the formula  $\frac{s-v}{2\theta\sqrt{2l}}$  which we gave last week, and

which we assumed would have been recognised by our correspondent as holding good only for comparatively small angles. The fact that it applies it to the case of a swing of 40 degs. confirms us in our belief that his previous conclusions were made in ignorance of it. Even with the inversion of the formula which we see our correspondent

is now recognised, we are unable to see how the constant  $\frac{2}{\pi}$  makes the necessary correction for the harmonic motion of the pendulum. It appears to us mathematically impossible for it to do so.—Eds., B.J.P.]

#### NEW APPARATUS.

To the Editors.

Gentlemen,—May I be permitted to endorse the remarks on the subject of the necessity for examination of new apparatus which appear upon page 223 of your present issue? I have just purchased a new 1-1 plate set by a first-class firm, and on looking over it immediately on arrival I found that the lens was scratched across the centre of the front combination, and the iris diaphragm was out of order. It worked all right down to  $f/32$ , but from there two or three of the leaves stuck, and the diaphragm assumed an egg shape. The tripod supplied was split right across, and one of the dark slide cutters had a slight crack in it. I enclose for your information the maker's name, and my card.—I am, Sirs, yours faithfully,  
Newcastle-on-Tyne. March 24, 1906. A PROFESSIONAL.

#### PHOTOGRAPHY FOR THE L.C.C.

To the Editors.

Gentlemen,—As one of the four firms invited to tender for the photographic work required by the London County Council, and in reference to your remarks, we venture to give you the following information, which we have no doubt will be of interest to many of your readers:—

The size of each negative referred to in your remarks last week was to be 12 by 10, and the price quoted to include "travelling and other expenses or charges for carriage, packing cases and packing,

and the supply of such negatives and prints as might be ordered for delivery at places specified by the Council."

These particulars are from the tender form, our own tender being, unfortunately, not successful.—We are, Sirs, your obedient servants,  
CLEMPSON AND HUTCHINSON.

Chichester House, Chancery Lane, London.

March 21, 1906.

#### CONTINENTAL TRADE METHODS.

To the Editors.

Gentlemen,—When travelling on the Continent I have, as an amateur photographer, had occasion to note with interest the up-to-date lines on which the photographic supply business is carried on in Germany. One firm, especially that of Soennecker and Co., in Munich, seems to me quite unique in the way it studies the interests of its customers. Under the auspices of Dr. Hauberisser, a photochemist whose name is not unknown in the English trade periodicals, courses of instruction in photography are given gratis, frequent lectures with illustrations, and every possible assistance is afforded; an original up-to-date photographic periodical is placed at the disposal of customers, and it is thought to stimulate amateurs to produce work of the highest class by offering prizes of considerable value for the best photographs. It is surprising what a wide range of the art is covered by the lectures, such as photography in natural colours, the improvement of indifferent negatives, demonstrations of the newest styles of printing, etc., and even amateurs of many years' standing will always find some new subject which is interesting. No doubt if something of this style was started by our English photographic supply companies it would meet with popular approval and support.—Yours truly,  
H. WRIGHT.

64, Lichfield Road, Stafford.

[We would remind our correspondent that the methods he describes and others which he does not mention are adopted by a number of leading firms in this country. A paragraph on another page mentions, by a coincidence, a course of lectures offered by a Liverpool firm to its customers.—Eds., B.J.P.]

#### PLATINOTYPE PAPERS.

To the Editors.

Gentlemen,—We have to inform you that owing to the very great increase in the price of platinum, we have been most reluctantly compelled to raise the prices of our papers. As you are probably aware, the price of platinum has increased in the last few years from about 25s. to 100s. per ounce.—We are, dear sirs, faithfully yours,  
THE PLATINOTYPE COMPANY.

22, Bloomsbury Street, New Oxford Street,

London, W.C., March 21, 1906.

[We give in another column the new scale of prices for platinotype papers.—Eds. B.J.P.]

ABERDEEN PHOTO ART CLUB.—A lecture on "Portraiture and Retouching" was given by Mr. W. Dunn, a well-known professional of the Granite City. In urging the members to give more attention to portraiture, he said that a studio and expensive apparatus were not essential to the producing of high-class portraits. The light from an ordinary window could be so controlled as to give beautiful effects, and he showed some fine specimens of work so produced. It was necessary, however, to acquire technical skill, both in the making of the negative and in producing the picture. Technical knowledge, however, would not produce a work of art in the real sense. Photography was easy up to a certain point. The difficulty began when a certain conception had to be portrayed and a certain character delineated. Artistic temperament could be cultivated, he said. Aim high, strive to make a good likeness. Delineate character. Here he envied the amateur the leisure in which he had ample opportunity of thoroughly knowing his subject. He spoke of methods in portraiture, and referred in high terms to the excellent work of Mrs. Margaret Cameron and Mr. Coburn. Much had been written regarding the "artistic lens." He had practical experience of its excellence, and showed by specimens the softness and beauty of the results produced by it. Much retouching was not necessary, and the lecturer showed by negatives how such could be done with care and practice by the merest tyro. Retouching was, he said, the curse of the professional. Give a professional retoucher a negative to work on and he would stipple the face all over, destroying every semblance of flesh tints and obliterating every line and wrinkle, producing the commercial article that appealed to and was in demand by the man in the street. The result, however, was neither a likeness nor a picture. At the close Mr. Dunn showed a number of portraits which bore out in a marked degree what he had been saying.

## Meetings of Societies.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, March 27, the President (Major-General Waterhouse) in the chair. Mr. W. Gamble exhibited a new spectroscopic camera by Mr. F. E. Ives, somewhat resembling the Tallent camera. The grating replica, however, was cemented between two prisms of 7 degrees, and was mounted with the collimator and slit in a separate box which was instantly removable from the camera proper of the apparatus, and could be then used as a direct-vision spectroscope. Mr. T. Thorne Baker, F.C.S., then read a paper on "Spectro-Photometry applied to Chemical Analysis." He first described the spectrograph camera necessary to obtain the necessary resolution of the fine lines. The instrument used by him was of the prism grating type, and 24 inches in length, and of resolving power 2,000. An equally important factor for resolution was a plate of fine grain. He had prepared an emulsion of fine grain and speed, 200 H. and D., which he colour-sensitised with

homocol and a black dye. The "resolving coefficient" necessary for spectroscopic work was .083 mm., but he was able to obtain a figure of .0025, combined with the rapidity above-mentioned. Mr. Baker described the precautions necessary in making qualitative analysis by spectrography, and instanced as tests which were usefully made by it for commercial purposes, the detection of iron in sodium chloride, and of calcium in barium chloride. Mr. C. P. Butler thought .001 mm. a large figure for grain; .03 was considered a coarse plate, and a photo-mechanical plate had a grain one-quarter of this size. Mr. C. E. Kenneth Mees thought that spectrographic methods were more useful at a later stage of a qualitative chemical analysis than as preliminary tests for the recognition of elements. The fault of the spectrographic method was that the prominence and number of the lines were not in any way proportional to the relative quantity of the elements in the mixture. An element might give a number of lines and yet be present in quantity which was unrecognisable by chemical tests, and of no practical importance. Mr. S. E. Sheppard said that an average grain of a fast plate was .004, and of a slow one .0013, but the definition of permissible grain was a complex matter, and required to be considered in reference to the conditions under which the plate was to be used. A hearty vote of thanks to Mr. Baker concluded the meeting.

SOUTHAMPTON CAMERA CLUB.—On March 24, Mr. W. R. Kay lectured on the "Bernese Oberland." "The Playground of Europe" as the lecturer styled this most beautiful district of the Swiss Alps, formed a most delightful medium by which a wealth of pictorial beauty was displayed. First came pictures of Old Berne, with its cathedral and its wonderful bridges over the Aar, and its equally wonderful river scenery; then Thun, with its old world buildings and its quaint costumes. Then followed a glimpse at the modest Niesen, and at Interlaken with its many beauties. Approaching the Alps by way of Brienz, the lecturer showed the beauties of the Schynge Platte. Some splendid pictures were shown of the Stabach Fall, with its 720 feet drop, and of Murren, the last stopping-place of the train. From this point the wonders of the mountains themselves were entered upon first; the Jungfrau, with its dazzling snow-fields; the sombre black Mönch, with its forbidding masses of black rock, or the Eiger in all its solid beauty. In the illustrations were shown in succession the mighty Wetterhorn, the Schreckhorn, and Finsternhorn. After this the lecturer passed to Grindelwald, with its quaint chalets, the gorge of the Lutschine, and then to the glaciers which abound in the district.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday, the 21st inst. (Mr. Arthur B. Fry in the chair), Mr. E. T. Holding visited the society and lectured upon figure studies. He said that a comparison of the arts of fifty years ago and to-day showed a great improvement. Moreover, photography had to-day placed draftsmanship within the reach of all, for if the camera were used with knowledge and intelligence one could depict tones of the most delicate degree. The user must, however, possess the sense of what was beautiful. Mr. Holding suggested that the study of modern paintings was more to the advantage of the photographer than those of the old masters, because photography is a modern art, and is more in touch with modern life and ideas, yet the study of old masters was an education, inasmuch as one could study the lighting, and the light and shade; and whatever printing process was used, light and shade was the groundwork of the beautiful. The personality of the worker decided the results. He presented things as he saw them; composition was like humour—it must come spontaneously, and the resulting picture must be obtained by the aid of light and shade. The principal point should never be central, and one should keep in mind that the art of composition was to hide the fact that composition had been used or called into aid at all. A well-balanced picture was one in which the lights and shades balanced each other. Sharpness of focus must be decided by the photographer, and either extreme sharpness or fuzziness might be used, each forming the key to success in varying pictures. A single long focus lens would give a broader and more complete diffusion than a doublet. To simplify was to strengthen. The worker, therefore, should determine the principal effect of the subject and strengthen it. Details must be shown, but they must be essentials. The would-be historical photographer must walk very carefully, as he had many pitfalls to contend with. For home work a room at the top of the house, with a blind that could

raised from the bottom, and two pairs of curtains—one white and transparent and the other of a slightly more opaque nature—were recommended, as various effects of lighting could by their means be obtained. Let the models as far as possible pose themselves, give them the idea that was wanted, if possible, by a rough sketch, get them interested, and they would, as a rule, fall at once into the proper pose. With children a box of chocolate was a very useful thing to have at hand, but on no account let the young sitter think that she is to be made use of. An ordinary long-focus field camera would answer every purpose. It must work, however, at an aperture that would allow of quick exposure being given when wanted. He personally used a Ross at  $f/5.6$ , but often found that a single combination gave the better result. It was sound advice to use the slowest plate that the subject would allow, but at times one wished for a plate four times the speed of the fastest obtainable, hence the choice must be left to the workers. A discussion, in which Messrs. Teape, S. H. Fry, Child, Bayley, and others took part, followed, most of whom thought that Mr. Holding had treated the subject in a masterly manner.

**BRISTOL PHOTOGRAPHIC CLUB.**—"The Possibility of Portraiture in colour" was the title of a lecture and demonstration given last week by Mr. S. E. Neame, who has already made a name for himself by his charming studies of heads and drapery. Mr. Neame demonstrated in detail the Sanger-Shepherd three-colour process making transparencies in natural colours, as in his opinion this is the best and simplest method at present available. The serious drawback to the use of this or any other "colour" process for portraiture is the long exposure necessary, three minutes about the minimum and five minutes the average time required, even under the best conditions of lighting, and with a lens aperture of  $f/3$ . However, with careful—i.e., restful—posing and a quiet sitter, it is possible to give a total exposure of five minutes about any movement being apparent in the three negatives. The sitter must be supported either by the arms of the sitter, a head-rest, or the background, but the absolute necessity for a comfortable position is not altogether a disadvantage, for it imparts a useful quality to the final result, a quality which was much valued by the old masters in their paintings, but which is often neglected by photographers. It is essential that the three negatives should coincide, for the movement of even a finger spoils the final result. For relative exposures required under the red, green, and blue lenses, using a Cadett "spectrum" plate, are approximately in the proportion of 40:10:4, but the proportions vary with each batch of plates, and it is necessary to make a trial set of exposures upon a white object, such as a piece of white blotting-paper, well marked up. With correct relative exposures the white object will be represented of equal density in the three negatives. To determine the absolute time of exposure, Mr. Neame gave the following rule—that the time taken by Watkin's actinometer paper to darken to standard tint is equal to the exposure required through the red screen, using a Cadett "spectrum" plate and a lens aperture of  $f/8$ . Mr. Neame showed several fine examples of portrait work by himself and others of various subjects by Messrs. Sanger-Shepherd and Co., but, summing up, he considered that portraiture in natural colours could not come into general use until the time of exposure was greatly shortened.

**DUNDEE PHOTOGRAPHIC SOCIETY.**—The annual lantern slide competition was held on Thursday, the 22nd, in the Queen's Hall, Dundee, the President, Mr. J. T. Cundall, B.Sc., in the chair, and notes and descriptions of the slides being read by Mr. R. C. Colm. About 500 slides were shown in the members' competition, while for exhibition thirty-six very beautiful Japanese coloured slides lent by Mr. J. M. Pillman, also slides from Messrs. J. F. Hie, John Burns, and Archibald Hepburn, together with a number of the latest cinematograph films. Medals were awarded as follows:—Archibald Watson, Glasgow; John M. Comrie, Ardross; George A. Hall, Edinburgh; Arthur Scott, Newcastle-on-Tyne; Thos. Kent, Kirkwall. Honourable mention: J. D. Brown, Dundee. There was a large attendance of the general public members. Mr. Haddow had charge of the cinematograph, and the Society's lanternist, Mr. J. M. Brnks, worked the electric lantern.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- H. Dunning, 12, Bridge Street, Usk, Mon. Photograph of H. A. Williams, M.P.H., and Three Foxhounds.
- W. Brown, 9, Gilmour Street, Paisley, Scotland. Photograph of the Rev. A. B. Scott. Two Photographs of the Rev. D. J. Allison.
- T. E. Scholey, 2, Sutton Bank, Manchester Road, Broadheath, Altrincham, Cheshire. Photograph of Mr. and Mrs. W. J. Crossley and Driver in Motor Car.
- P. Beales, 21, Silver Street, Gainsboro', Lincoln. Photograph of Grave of the late Mr. H. D. Marshall, New Cemetery, Gainsboro'.
- P. Moll, 208, Battersea Park Road, London. Photograph of Rt. Hon. John Burns, M.P.
- J. W. Stephens, 84, Cobden Street, Leicester. Three Photographs of Police Constable J. W. Stevens of Leicester.
- H. E. Cull, 169, St. Alban's Road, Watford, Herts. Four Photographs:—Lord Essex Lodge, Longspring, Watford. Watford Fire Brigade Practice. Callowland Farm House, Watford. Watford Fire Brigade, Turn Out.
- J. Thompson, Crane's Buildings, Wellington Place, Belfast. Two Photographs of the Rev. Father D. McCashin.
- A. Hinkins, The Studio, Exchange Street, Retford. Photograph of a Group of Girls in Fancy Dress in "The Taming of the Shrew."

**OBSCURING GLASS.**—Can you inform me of an easy method of making the ordinary glass in a verandah appear as ground glass?—S. H. Dagg (Allahabad).

The glass may be obscured by painting it over with thin white paint and stippling it over with a dry brush. Or it may be stippled over with starch, or flour paste, to which a little common whiting has been added. The latter has the advantage that it can, at any time, be easily cleaned off.

**REGISTRATION OF NAME.**—I am thinking of registering the name of an article I intend putting on the market. Can you advise me as to method of procedure, and what it would cost me?—W. H. SEAGER.

The name must be registered under the Trade Marks Act. If you write, enclosing a penny stamp, to the Comptroller, the Patent Office, Trade Marks Branch, 25, Southampton Buildings, Chancery Lane, for the "Instructions to Persons Wishing to Register Trade Marks," a copy will be sent you. From this you will see how to proceed. The application form is five shillings, and the registration fee one pound.

**STUDIO QUERY.**—I am building a studio, 36ft. x 18ft. (outside), and find that, according to the bye-laws here all wooden buildings must be at least 8ft. from the footpath, so I am bound to set my place back that distance. The south side comes on to the street, but the north light is quite unobstructed. I am having 12ft. of glass at the sides (8ft. to eaves), and on both slopes of the roof. 1. Would you advise ground or plain glass. 2. What colour blinds would you suggest, and on what principle? 3. How many panes, and what colours for dark-room window? It will be about 12 inches square. I thought two ruby and one orange. 4. Should my backgrounds be on stretchers, and if so, how can I manage with foreground continuations?—BEGINNER.

1. For the south side we should advise ground glass, and for the north plain. Fluted glass might be used in the north side, which will prevent persons in the street seeing into the studio. As both ends of the studio could be used there seems little need of the south side being glazed at all. 2. Black or very dark green for the south side, a pale green for the north blinds to pull down for the roof, and curtains for the sides. 3. One thickness of ruby and one of orange will be safe, if the glass is of the right kind. 4. By attaching them temporarily to the bottom of the back ground frame.

B. H.—Messrs. Houghton's, Limited, we believe, are the agents, if not the makers.

RETOUCHING (Reply to E. E. L.).—Were it not for your very weak modelling on the forehead, we should consider you had been practising for six years rather than six months, as your touch is soft and blended, and far in advance of the majority of the specimens sent to us. The treatment of the forehead should have been more tender, and following the natural formation closer, especially on the shadow side approaching the temple. The line from nostril to mouth is also badly worked, and should be softened into its depth from the cheek side with nice gradation, and yet fully retain its force and character. Your retouching is more than promising, but be careful of overworking.

HOOSIER.—It is contrary to our custom to make such comparisons. Both papers are very largely used, therefore either should answer your purpose.

COPYRIGHT.—Last year I bought from Mrs. —, the studio camera and accessories, the property of her late husband. My employer and I agreed partnership whether the goods were turned into cash or put into a studio. The receipt was made out in his name. Amongst the goods I found some negatives of the Painted Hall, Greenwich. Since then the whole of the goods were given to me, and removed to my own premises, some being sold. On leaving my employer I lent the negatives to him for postcard work, and I have recently made negatives for my present employer from prints in my possession. Unfortunately, I have no receipts for any of these transactions. It is impossible for us to tell who is the author of these negatives. If Mr. — (who died six months ago), they were undoubtedly taken many years ago. We have been demanded (by a solicitor) to give up all negatives and prints immediately. It is my opinion that not knowing who is the author of the negatives, it is as much my property as anybody's. In fact, common property.—H. J. G. URGENT.

If the negatives were sold, supposing there was a copyright in them, and the copyright was not assigned with them to the purchaser, it has ceased to exist. It has become public property. If the facts be as stated, the demand by the solicitor is simply "bluff."

S. A. C.—The only apparatus of the kind we can suggest are the changing boxes, carrying twenty films in sheaths.

ARTISTIC LENSES.—I should be greatly obliged if you would kindly answer me the following questions:—1. Is the adjustable landscape suitable for indoor portraiture, in room 15ft. x 12ft., used with half-plate field camera, of 20 inches extension? 2. What is largest working aperture, focal length, and cost? 3. What would be the shortest allowable distance between sitter and camera, in taking large heads on half-plate, without risk of noticeable faulty perspective? 4. Is there any book written in English dealing fully with these lenses?—V. HEX.

1. The adjustable landscape lens could be used. 2. The aperture and the focus is adjustable according to the distance of the object from the lens (see footnote, 2nd column, p. 188, of March 9, and, on the same page, half-way down the second column). The cost depends upon whether the lenses are made of best crown or St. Gobain crown (see advt., p. viii., of last week's issue). 3. The distance should be about 10ft. 4. There is no English work on these lenses.

D. CARNEGIE.—Many thanks for prints, which we will examine.

POSITIVES DIRECT.—Kindly give directions as to how to produce a positive directly from an ordinary negative, i.e., how I may convert a negative into a positive by chemical means. I know of the method involving the use of hydrogen peroxide on the unfixed negative, and subsequent staining, but as I am employing the positives in colour photography, the instability of the peroxide and the difficulty of dissolving off the acted-on gelatine, make results uncertain. The positives into which I wish to directly convert the negatives should be, if possible, of a neutral colour, e.g., black and white.—ALFRED N. GOLDSMITH.

There should be no difficulty in dissolving off the gelatine with hydrogen peroxide, particularly if Merck's 30 per cent. solution is employed, and this will keep well in the dark, provided a developer has been used which does not tan the gelatine. After

development and before fixing, the negative is well washed and then treated to a 2 per cent. solution of chromic acid and well rocked. After about the lapse of a minute the plate may be examined by faint daylight, and the acid must be allowed to act till the black image is completely converted into red chromate of silver. Then immerse the plate in a 20 per cent. solution of sodium sulphite till the chromate of silver is dissolved, and then develop the previously unreduced bromide with a strong developer (such as metol-hydroquinone or amidol). It is frequently necessary in order to obtain a sufficiently contrasty positive to place the negative before treating with chromic acid glass down on some black surface, and expose the film to daylight till the shadows just turn blue-grey, but this is dependent on the make of plate.

COLOUR FILTERS.—Some weeks ago you kindly answered some questions of mine in the B.J.P. on the making of colour-filters. I am now in difficulty about drying the dyed gelatine films. The film dries with a grained appearance, although the gelatine is three times thoroughly filtered. On examining this under the microscope I find it is composed of very fine crystals. I use Nelson's No. 1 photographic gelatine, and dry in a current of air at a temperature of 70 degs. It is the green and red filters I have the most trouble with. Any information you can give that may help me out of this difficulty will greatly oblige.—A. M. A. C.

This trouble we do not understand, provided our instructions as to the use of the particular dyes and distilled water were carefully carried out. We have not met with it, and should like to see one of the filters showing this defect. Very frequently the gelatine will have a slight granular appearance when dry, but this disappears when two filters are cemented together, and does no harm.

A WORKER.—We do not reply to anonymous queries.

A QUESTION OF PRICE.—I should be much obliged if you would say what you would consider to be a fair and reasonable charge to make for the following order. The order is from a firm of organ builders, and is—"to make from designs and tracings of organs,  $\frac{1}{2}$  plate negatives, and supply three mounted prints from each, plain mounts." The number of designs to copy is seven, which means seven negatives and twenty-one prints (bromide). I thought 2s. 6d. for each first print and 1s. per print after. This they consider to be too much. Of course, doing seven at one time after the first design is fixed up and focussed, means less time is taken than would be the case if only one design was to be copied at a time, but for future orders, probably only one, or at most two designs, would be given me to do.—"H. TMS."

We think the price a reasonable and moderate one. We cannot say whether it will pay you to lower it, as we do not know your cost of production.

ALF. SMITH.—Next week.

ARTISTIC LENSES.—Is it possible that the effect produced by the new "artistic lenses" can be identical with the effect produced by using stained diaphragms, as described on page 714, "B.J. Almanac" of 1894? Are both due to chromatic aberration?—INTERESTED.

The action is quite distinct, as the effects of chromatic aberration are modified by the diaphragm.

\*\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The expert photographic assistant is gradually improving his position: the less skilled worker is as surely losing ground." That the conclusion of Mr. John A. Randall from an analysis of wages in 1905 compared with those of past years. (P. 269.)

ens-testing methods as employed by Messrs. Beck and Chalmers demonstrated before the Optical Society last week. (P. 271.)

ortraiture with flaming arcs and orthochromatic plates is discussed in reference to economy and efficiency by Mr. Arthur Payne. (P. 278.)

structions for the making of photographic enamels by the iron order process are given by an American worker. (P. 268.)

etching methods applied to landscape negatives are detailed in article by Mr. Arthur Whiting. (P. 267.)

reviewing the exhibitions of the Photo-Secession a Transatlantic per gives his impressions of J. Craig Annan and Fredk. H. Evans. (P. 267.)

atters of importance in the making of coloured miniatures to be in large numbers are considered on page 262.

intensification in Theory and Practice.—The first of a series of papers on the use of the modern intensifiers commences on page 264.

practical notes on the working of the double transfer carbon process given in the series of chapters on printing processes. (P. 263.)

ethods of gum printing were demonstrated before the North Essex Society last week by Mr. J. C. S. Mummery. (P. 276.)

efore the Watford Camera Club, Mr. E. Seymour gave a method of soft prints on gaslight papers. (P. 276.)

## EX CATHEDRA.

### Duty Free Alcohol.

It will be remembered that a year or two back a Departmental Committee was appointed to inquire into the use of duty-free alcohol for industrial purposes. In the House of Commons one day last week it was stated in reply to a question that the conditions under which alcohol should be procurable for industrial purposes were examined and reported upon a year ago, and the recommendations were embodied in the Revenue Bill brought in last session. The present Government hoped to be able to introduce legislation on the subject at an early date. Alcohol is not so much required in photography as it was in the collodion days, and for the purposes it is now used for the methylated spirit does just as well, except for the manufacture of collodion. If duty-free spirit were allowed to be used for that, its price could be very considerably reduced. Collodion contains about equal parts of ether and alcohol, and at the present the cost of the latter is three times that of the former. If it were not for the duty, pure spirit could be sold for the same price, or even less, than that of methylated spirit.

### Carrying Coals to Newcastle.

In the "Inland Printer" (American) for March, lately to hand, there is contained an advertisement for a works manager wanted by first-class firm of photo engravers in England; only experienced men well up in all branches need apply; salary £400 per annum. One would have thought it unnecessary to go to America to get a suitable manager; in fact, in the light of Mr. Gamble's account of his observations in America, it is doubtful if men there are so "all-round" as they are in England. We happen to know of two similar advertisements appearing in the same paper from English establishments, and both vacancies were filled, not by Americans, but by Englishmen who had only been in America for a short time.

\* \* \*

### Stripping Bichromated Albumen Paper.

A query we have had this week from a correspondent is a somewhat novel one, and for this reason we deal with it here instead of in the usual "Answers" column. The writer wishes to know, in effect, if albumen paper, sensitised with bichromate of potash, can be used in the same way as ordinary carbon tissue—that is, printed and then transferred and developed upon another support. Now if ordinary albumen paper be sensitised with a solution of bichromate of potash, and printed, the light will penetrate through the film in the more transparent portions of the negative to the paper, hence is could not be stripped off for development. In the case of carbon tissue, the pigment prevents the light from penetrating very deeply, so that there is always a soluble layer of gelatine intervening between the printed image and the

paper; consequently, when the tissue is mounted on its support and put into the warm water for development, this layer dissolves and liberates the paper upon which the pigmented gelatine was spread, and allows of the washing away of the unaltered, by light, portions. These conditions have to be observed if any other colloid than gelatine is desired to be employed, and the printed image in half-tone has to be transferred from the paper on which it was printed. It is quite conceivable, though we have not tried it, that if paper were coated with a much thicker layer of albumen than the ordinary one, and the albumen contained sufficient of a pigment to prevent the action of light going right through to the paper, that it might be transferred and developed in the same way as an ordinary carbon picture. Of course, the development would have to be done in cold or quite tepid water, as hot would coagulate the albumen and make it insoluble. In place of albumen it is quite possible that gum arabic, which our correspondent says will answer his purpose as well, might be made to serve. In any case we should surmise that the metal plate upon which the image is desired would require to have a coating of insoluble gelatine, such as that on the usual single transfer paper. One way in which an albumen picture in bichromated albumen may be transferred to a metal plate may be mentioned, but it is only applicable to line subjects. The paper is first coated with a thin solution of indiarubber and then with the bichromated albumen, printed, and afterwards developed in cold water—that is, the unacted upon portions dissolved away. The wet print is squeezed down upon the metal plate previously coated with insoluble gelatine, and allowed to dry. Then if the back of the paper be sponged over with benzol it can be stripped off, leaving the albumen on the plate.

### Portraiture 2,000 Years Ago.

Should a church service ever form part of a photographic function or convention it will not be difficult to find a text for the sermon. We will suggest one which would appeal particularly to professional photographers—perhaps the Rev. F. C. Lambert may be glad to file a note of it. In Ecclesiastes (revised version) we read:—"They that cut gravings of signets, his diligence is to make great variety. He will set his heart to preserve likeness in his portraiture, and will be wakeful to finish his work." This sums up in a very few words the qualities that go to make a successful photographer. Human nature is, after all, much the same to-day as it has ever been, and our readers will not be surprised to see that customers of 2,000 years ago wanted their portraits to be likenesses, and wanted them quickly after placing their order. The "diligence to make great variety" is possibly a point which needs some attention nowadays. There is a great tendency for work to become stereotyped, and the only way to avoid this is the way indicated—"diligence," or, in other words, a careful study of the methods of obtaining variety without losing characteristic pose or expression. We might, in fact, say that variety should be obtained by observing and recording characteristic pose instead of fixing the sitter in some preconceived position of one's own.

### Free Sittings.

In several issues of late reference has been made to the forthcoming "single-picture exhibition," and congress, inaugurated by the Professional Photographers' Society of New York. It is to be a purely business meeting and for purely business purposes. Last week we published a list of twenty-three subjects set down for discussion, all of which are important to the profession there, and equally so in this country. One of the foremost subjects we see is, "Under what

circumstances is the photographer warranted in offering a free sitting?" If the free sitting business is carried on in the States as it now is here, the question is a very important one indeed. Some persons have an idea that the invitation, or free, sittings system is a somewhat modern innovation, but, as a matter of fact, it is nothing of the kind. It is almost as old as photography itself, or rather as old as the collodion process. In the middle fifties a firm of photographers in the City made a feature of securing the portraits of the leading men in science and members of scientific societies for publication, and a very fine collection of portraits they obtained. The pictures were of the whole plate size, and were published at half-a-crown a copy. When the "carte de visite" came in, several of the leading portraitists made a feature of portraits of theatricals, male and female; others went in for members of Parliament, others for medical men, the clergy, etc. The portraits were, of course, all taken at invitation sittings. Yet all this is quite a different thing from the present system of giving free sittings to nobodies. In the instances we are recalling only those who were of note in their particular spheres received invitations, and the photographers relied solely upon the publication of the portraits for their profit. Now, in many cases, a free sitting is given to anyone; the photographer relies only on the chance that the sitter may order copies for his own use. We were recently told that a photographer in a rather fashionable suburb of London was employing female canvassers, going from house to house inviting people to go and sit for their portraits, for which no charge would be made. The sitter was to be presented with a copy of cabinet size, the photographer depending for his profit on the chance that further copies might be ordered. Whether the scheme pays or not, it is certainly playing photography very low. We somewhat doubt if it is being played so low as this in the States, but if it is, it will be interesting to see what remedy the Professional Photographers' Society of New York can suggest.

\* \* \*

### Coloured Miniatures.

Several correspondents having recently addressed queries to us as to the methods of preparing the class of miniature which can be produced in numbers at a low price, the following hints will perhaps be of value, also to others desirous of working such a side line. All that is necessary is a good clear print, of the required size, in gelatino-chloride, unmounted. The colouring is very simple, and could be done by the "reception room lady" after a few lessons. The colours needed are only three: red, yellow, and blue aniline dyes, but they must be colours that will mix. Red will usually combine with either of the others, but some samples of blue and yellow will not combine to form green, but precipitate one another to a muddy mess at the bottom. But any of the firms who make a special feature of dyes will supply a yellow and blue that will combine. Having procured these three colours saturated solutions should be made. The print needs no preparation except wetting; the surface moisture is removed with a clean cloth and the print is ready. A little of each of the three colours is poured out into separate saucers, and with a clean brush a little red is put into a clean saucer and considerably diluted, and a small proportion of yellow added, to form a flesh tint. It should be tried on a waste print. The brush is well filled with colour and mopped over the face, and almost at once the colour on the surface is wiped off with a piece of clean soft rag, rather moist, which is held in the left hand ready to take up the surplus colour. The tint left on, or rather in, the print will perhaps be too pale after only one application, and a second or third application of the brush may be necessary, always followed immediately by the

can rag. Any colour that is needed can be obtained by mixing the three colours in different proportions. For small parts, such as the lips and eyes, a fine sable should be used and the colour should be less diluted. It is surprising what pretty effects can be secured by these simple means, depending on the taste and skill of the wielder of the brush. After the colouring of the print is finished it should be allowed to become "bone dry" before doing anything more with it. It will have an unfinished appearance and needs to be glazed; this may be done in several ways, by cementing it upon a piece of celluloid, as recommended for "photo-buttons," or it may be attached to the inner side of the glass of the locket it is intended to fill, with a little warm gelatine solution, or it can be enamelled by squeegeeing down upon a piece of clean French-chalked glass, or waxed ferrotype plate. If the print is thoroughly dry after colouring, it may be moistened for enamelling without fear of the colours running, but it must not be left soaking too long or the colours will be washed out.

### PRINTING PROCESSES.

#### XX.—CARBON—DOUBLE TRANSFER.\*

In the previous articles of this series the single transfer process of working was very fully dealt with, but with that method the pictures are reversed as regards right and left unless a laterally reversed negative has been employed. If carbon prints are required the right way out from ordinary negatives, the pictures must be developed on some support from which they can be afterwards transferred to a permanent one. Here we have a great choice of materials on which the pictures can be developed. It may be a rigid one, such as plain glass, round glass, zinc; or it may be a flexible one, such as paper which has had a coating of insoluble gelatine and one of shellac applied to it; or it may be paper coated with a solution of indiarubber. The former is what is universally employed in this country, and is known commercially as "flexible support." The latter is, however, largely used on the Continent. It may be mentioned at whatever support the print is developed upon, the finished picture will have its surface: if developed upon matt surface glass, say, smothed opal, which is much better for the purpose, the picture will have a matt surface; on plain glass, a polished one; if on the usual commercial flexible support, it will possess about the same surface and gloss as that of an ordinary albumen silver print. Whatever temporary support be chosen, it must be so prepared that it holds the image firmly during the development, and will readily yield it up to a permanent one when required; an attenuated film of beeswax fulfils its end perfectly.

We will first deal with the ordinary flexible support as that in the one most commonly employed in everyday work. Suitable waxing solution is as under:—

White rosin .....	$\frac{3}{4}$ ounce.
Genuine beeswax .....	$\frac{1}{4}$ ounce.
Rectified spirit of turpentine	20 ounces.

When the rosin and wax are dissolved the solution is ready for use. The support should be an inch or so larger each way than the picture that is to be developed upon it. A little of the solution is poured on and then only rubbed over with a piece of flannel. After resting a few minutes, during which time other pieces may be similarly treated, the wax is cleaned, or rather polished, with another piece of flannel until the surface is free from streakiness and looks evenly polished. The same

flannels will serve for many pieces—indeed, up to a certain point they improve by use. The waxing is best done a few hours before the support is used, so as to allow all traces of the turpentine to evaporate. If, instead of the flexible support, a rigid one be used, and a very general one is smothed pot opal glass, which yields pictures with an excellent matt surface, the same waxing solution will answer. The glass is first thoroughly cleaned with soap and water, well rinsed, and allowed to dry. It is then waxed in the same way as the flexible support, but not so much solution should be used as to fill up the grain of the glass. In using opal glass some workers prefer to coat it with a rather thin enamel collodion, as this gives a somewhat greater transparency to the shadows of the pictures. In this case the glass may be rubbed over with French chalk and then dusted. This is less trouble than waxing, and answers the purpose quite as well. After the collodion has been allowed to set thoroughly the plate is put into cold water until all appearance of greasiness has disappeared. If a highly enamelled surface is desired, plain glass should be used. This, after being thoroughly cleaned, is polished with French chalk and then coated with the ordinary enamel collodion and treated in the same way as in the case with opal glass. The support, whatever is used, being ready, the exposed tissue is squeegeed upon it just as if the single transfer paper were being used. If, however, the glass has been coated with collodion, a piece of thin indiarubber cloth—that known as nursery sheeting is the best—is laid over the plate to protect the collodion film while squeegeeing. The manipulations in the development, etc., are precisely the same as in the single transfer method, which need not be further referred to. It must, however, be borne in mind that prints on a temporary support will not bear the same rough treatment as those on single transfer paper. For example, they will not stand such hot water in reducing over-exposures, as there would be some little risk of blistering. Also any "faking" that may be desired must be more tenderly done than when the prints are on single transfer paper. For these reasons over-exposure should be avoided as much as possible, and when it happens a longer soaking and in water at a moderate temperature is better than a shorter treatment in that at a greater heat. Furthermore, in this way the flexible support is not so much injured for future use as it would be if very hot water were employed. The pictures being developed are treated with alum, rinsed and allowed to dry spontaneously, and are then ready for transferring to their permanent support.

The double transfer paper, which is supplied commercially, is paper which has been coated with gelatine that has been rendered partially insoluble by chrome alum. If it be long soaked in warm water, or if the water be too hot, the coating will entirely dissolve, and the picture will then not transfer. Some workers place the transfer paper direct into water at a temperature of from 90 degrees to 100 degrees Fahr., but others prefer to soak it for ten minutes or so in cold before putting it into the warm. But whichever method be adopted, the paper should be left in the warm water until its surface has acquired a distinctly slimy feel on the surface. It is then ready for use. If the print is on the flexible support it should be allowed to soak for about a quarter of an hour in cold water before the softened transfer paper is applied. The coating of the latter having been got in the right condition, the picture on the support is put under it, in the warm water, and the two brought in contact, removed on to a glass plate, and the two squeegeed together. The squeegeeing should not be so heavily done as when mounting the exposed tissue on the support, as that would tend to press

\* Continued from page 143.

out the coating of the paper if that were made unnecessarily soft in the warm water. The prints are then pinned up and allowed to dry spontaneously. When thoroughly dry, and not before, they are stripped off. Should the pictures when stripped show any marks of the waxing solution, they may be removed by polishing them with a piece of flannel slightly moistened with turpentine. The same flexible support will serve for many prints, but it will, of course, require to be re-waxed each time.

If the pictures have been made on a rigid support the same procedure is followed in transferring them, except that if the glass had been collodionised the indiarubber cloth must be used to protect the edges of the film in the squeegeeing. If the film were torn the print would have a tendency to leave the plate before it was evenly dry all over. Should it be desired to retain the full enamel gloss when the picture is mounted, a second piece of softened transfer paper should be applied on the back of the first, after that has become surface dry; then the print can be mounted in the ordinary way without the loss of gloss. Indeed, worked in this way the carbon process is the easiest method of producing enamelled pictures. Spotting of them can be done with tube oil colours, diluted with turpentine, before the transfer paper is applied so that it does not show in the finished result.

From the flexible support the carbon picture may be transferred to any material, such as ivory, opal glass, metal, wood panel, or indeed to almost any homogeneous surface. The procedure is as follows:—An ounce of gelatine—Nelson's No. 1 is a very suitable one—is soaked in a pint of cold water till soft and then dissolved by heat. Twelve grains of chrome alum, dissolved in two ounces of warm water, are then added gradually, stirring well the while. This solution is then put into a dish, kept warm; the picture on the support and the material, whatever it may be, which has been well cleaned, are immersed in it, the two brought in contact and afterwards squeegeed in the usual way. When dry the support is stripped off. If the picture is to be coloured with water colour, it will be well to rub it over with a pledget of cotton wool, moistened with benzol to remove any traces of wax that may be on it, otherwise it will not take the colour freely. Carbon pictures on a rigid base, as ivory, which are to be coloured, are best printed from rather soft negatives, as then there is a thinner film of gelatine in the shadows than is the case when they are printed from more vigorous ones.

In the next and concluding article the sensitising of the tissue to suit different types of negatives will be dealt with.

## THE THEORY AND PRACTICE OF INTENSIFICATION.

### I.

THE intensification of negatives assumed many years ago a position of importance, inasmuch as, besides the occasional necessity for it which a badly exposed or developed plate gives rise to, it is a universal custom to intensify half-tone photo-mechanical negatives subsequent to their partial reduction. A great number of large and experienced firms of photo-engravers employ nothing but the mercury-ammonia method of intensification, and this method probably represents quite nine-tenths of those used at all, uranium only sharing a limited popularity. It is, however, very desirable to make use of any method which is more adapted to our work than others, and I shall endeavour to give, by combining mathematical with practical results, some better ideas than have hitherto been expressed as to the comparative results secured by the various procedures.

It is hardly necessary to observe that in order to obtain the best results the characteristics of the intensifier must correspond with the requirements of the negative. Thus a harsh, under-exposed negative will require such treatment as will produce greater intensification in the shadows than in the high-lights; a flat, over-exposed negative will require greater intensification in the high-lights than in the shadows; and a correctly-exposed but under-developed negative will require a proportional increase in density for each tone in the image. The necessity for the preliminary reduction of flat over-exposed negatives before intensification can be overcome by an intensifier which only adds density to the high-lights, whilst it reduces the shadows; that this is quite an easy matter will be seen later on. That certain methods of intensification are capable of acting in entirely different ways by modification is also evidenced by photometric investigation.

There is a growing tendency nowadays to supersede the older methods by more recent ones, such as the chromate bleacher with subsequent redevelopment, and the conversion of the silver into a haloid which will darken on exposure to light. But the old-fashioned mercuric chloride intensifier is capable of giving a very great variety of results, and it is only a matter of choosing

a suitable blackening agent to make it deal successfully with almost any class of negative.

Mercury is a metal which belongs, by reason of its chemical behaviour, to two families of metals, and is a member of the group which includes lead and silver, as well as of the divalent group which includes metals whose sulphides are not affected by dilute acids. There are thus two compounds of mercury with chlorine,  $Hg_2 Cl_2$  and  $Hg Cl_2$ , and it is probably to the ease with which a certain percentage of  $Hg Cl_2$  becomes ionised in aqueous solution that the efficacy of mercuric chloride is due.

We must always look upon a negative as being built up of tones, or minute portions, some of which are very dense, some less dense, some still less, and so on; the more opaque or dense portions are made up of correspondingly large deposits of silver, whilst in the lighter parts of a negative we have only a few small granules of reduced silver haloids, more widely separated from one another in the gelatine vehicle. Under certain conditions the dense "tones" become intensified, while the lesser tones obtain little intensification, and under different conditions again the dense tones receive intensification, whilst the lesser tones become so little changed that in the reblacking they actually lose some of their original density. This may be readily understood in the case of mercury, when we consider that its action during bleaching is to form a surface-coating containing silver chloride; the extremely small particles of metallic silver become converted entirely into silver chloride, and the reblacking agent being a solvent of silver chloride, it is completely removed in the second operation.

The conversion of the silver image by the mercuric bleaching bath is simply expressed by the equation,

although, according to many authorities, the chloride is a double compound expressed as  $Ag_2 Hg_2 Cl_4$  or  $Ag Hg Cl_2$ ; it seems more probable, however, that the two halides become formed side by side. Each atom of silver, by this operation, becomes richer by

re metallic atom, and, with the larger grains, which are metallic on the outside surface and sub-haloidal within, the grains which are superficial become similarly enriched. The image is formed by the action of ammonia on the bleached image may be expressed as  $\text{NH}_3 \cdot \text{Hg}_2 \text{Cl}$ , the silver chloride being reduced. But diverse opinions are held regarding the action of ammonium sulphite, which does not reblacken the image, but produces an intensification accompanied by brown coloration. It is assumed, for example, by Vogel that the mercurous sulphite reacts with sodium sulphite to form mercurous sulphite, which is soon decomposed, and gives metallic mercury and mercurous sulphite. According to analyses carried out by him, a compound of the metals mercury and silver was obtained in the proportion of 67.5:32. A compound of the formula  $\text{Ag}_x \text{Hg}_y \text{S}_z$  is suggested by Hauberisser, but the general opinion is that a sulphide is formed, despite the indication of it given by a brownish colour.

Reblackening with thiosulphates and various sulphites produces the same brown coloration of the image, so that one may reasonably infer that the action differs essentially from that of ammonium chloride.

The use of lead and silver compounds for intensifying has not met with any lasting approval, but the metals of the chromium and manganum series in particular—have been tried with a measure of success. The precipitation of an insoluble oxide made use of, which thus enriches the preliminary silver image, and there is every reason to believe that tungsten and manganum intensifiers can be found to equal those which are based on chromium. That molybdenum may be considered as equivalent to chromium, "photographically," is evident from the fact that an acid solution of ammonium dimolybdate has the same action on the negative as dichromate.

Metallurgically, any metal whose salts can be precipitated on the negative, and silver only, in a negative may be utilised for reblackening purposes. Thus, bismuth trinitrate was tried and gave a fair amount of success, and seems well worth further investigation; an acid solution of the nitrate is used, and in this case the action that can be observed takes place, but on finally treating the negative with a weak aqueous solution of ammonium sulphite, a very powerful intensification is effected.

Uranium has some interesting properties when employed for reblackening, the nature of which becomes evident on comparing the curves obtained by plotting the densities of the gradations in two negatives, one intensified with potassium ferricyanide over potassium ferrioxalate, the other with an excess of ferricyanide over uranium. The sepia compound precipitated on the image when excess of potassium ferricyanide is used has a preference for depositing upon the under-exposed parts, whilst the bright red deposit obtained when an excess of uranium is used does the reverse, i.e., intensifies the over-exposed parts to a greater comparative extent than the under-exposed parts. A great deal depends, however, on the character of the negative.

Proceeding further, let us look into the matter of reblackening more closely, and determine the effects of various reblackening agents. It is only natural that some agents will act in a different manner to others; for example, reblackening with thiosulphate may reasonably be expected to have a more drastic effect on the under-exposed portions of the negative than ammonia, being a more ready

reblackening agent. A comparative action of various reblackening baths was determined by making a number of negatives with the Hurter and Driffield sensitometer, identical in character, so that in each negative there were nine divisions, one which received no

light, and the other eight receiving exposures such that each division was twice as long exposed as the preceding division; the negatives were thus made up of nine divisions, each division being of a different density, so that the whole represented the various tones in an ordinary negative, from black to white.

Several of these strips were bleached with a solution of mercuric chloride and ammonium chloride, the proportions of the two salts being in accordance with their molecular weights, viz.,  $\text{HgCl}_2$  271, and  $(\text{Am Cl})_2$  107. The solution was decinormal in all experiments, the formula for a convenient quantity being:—

Ammonium chloride .....	2.7 gms.
Mercuric chloride .....	6.8 gms.
Distilled water .....	250 ccs.

The strips having been bleached altogether, and, of course, for the same time, they were then thoroughly washed and reblackened, each one with a different agent; ammonia (10 per cent. solution), sodium sulphite, sodium thiosulphate, and acetone sulphite were the four used in the first experiment. The intensified strips were next washed and dried, and each one read off in the photometer, the densities of each portion of a strip being plotted on a curve alongside of the unintensified or control strip.

The comparative curves are shown in the accompanying diagrams. Mercury and acetone sulphite and mercury and

ammonia gave very similar results, as will be readily seen. But with mercury and thiosulphate and mercury and sodium sulphite the weakest portions of the strips were actually reduced in density, whilst intensification was received only by the denser portions. Further experiments, in which a longer bleaching was given, showed the same result in the case of thiosulphate, but with sodium sulphite a slight increase in density was

generally observed in the weak portions, and intensification took place in good proportion, altering the gradations very

Fig. 4.

little indeed. Thus compare the readings obtained with strips before and after intensification as follows:—

#### I.—MERCURY AND SODIUM SULPHITE.

	Fog Portion.	1st Tone	2nd	3rd	4th	5th	6th
Control Strip .....	1.5	2.5	6.9	11.7	16.5	21.0	—
Intensified Strip .....	2.2	3.3	8.4	14.5	20.3	27.1	—
Control Strip .....	1.1	2.2	5.6	9.0	12.2	15.0	17.0
Intensified Strip .....	.9	2.2	6.5	11.4	16.2	19.5	23.1

Mercuric iodide and hypo gave a result similar to mercuric chloride and ammonia, but the effect on the gradation was

Fig. 5.

not so uneven. An ideal intensifier should add density to every tone in a negative in the same proportion; thus, take

any two points on the unintensified and the intensified curves, P1 and P2; the density for the same exposure (expressed is measured along the abscissa) is 2 for P1 and 2.7 for P2; that  $I_N$ , the intensification, is  $I_N = \frac{2.7}{2}$ , or 1.35; i.e.

intensifier has increased the density 1.35 times. Now take two points Q1 and Q2; the density for this exposure is respectively 5.6 and 8.2, so that  $I_N = \frac{8.2}{5.6}$ , or 1.46.

Clearly, then, in this case the more exposed portions of the negative receive more liberal intensification than the less exposed parts.

Now, this is obviously desirable in the case of an over-exposed, flat negative; but with an under-exposed, harsh negative we require an intensifier which will give us the greatest addition of density in the dark shadows, or least dense parts. For a properly exposed but insufficiently dense negative we require even intensification throughout, so that at any point  $I_N = k$ , where  $k$  is some constant.

The intensification of process (half-tone) negatives is usually carried out with mercury and ammonia, but mercury and sodium sulphate is obviously preferable, as we get with it very little density in the blacks and an actual cutting out of the faint portions, so that the dots are cleared in the reblacking; has yet to be ascertained whether thiosulphate prevents the corners of the dots from joining where desired, but this could be adjusted by the use of a suitable diaphragm in the exposure of the plate.

The foregoing remarks indicate that special attention is required in the selection of an intensifier suitable for under-exposed, harsh negatives, which will favour the deep shadows and have little effect upon the high-lights; that mercuric chloride and sodium sulphate form an excellent intensifier where an even—i.e., proportional—increment is required for each tone in the negative, provided that sufficient time be allowed for bleaching; and, finally, that by reblacking with thiosulphate it is easily possible to reduce the weakest tones in density whilst intensifying the high-lights, and that therefore this method is suitable for the intensification of flat negatives. Ammonium thiosulphate is preferable to the sodium salt.

The next chapter will treat more particularly of intensification with chromium and uranium.

T. THORNE BAKER.

## RETOUCHING LANDSCAPE NEGATIVES.

It frequently happens that landscape negatives are most disappointing owing to numerous eccentricities of varying or unsuitable light, wind, moving figures, etc., yielding results undesirable in the extreme. And whilst many spend a vast amount of time endeavouring to atone for the caprices of fate by chemical manipulation, is it not a wonder that so few place their landscape negatives upon the desk, and with pencil, stump, and knife engrave their knowledge of art upon the luckless film?

A few weeks ago the B.J. published some sinister remarks extracted from *T.P.'s Weekly* (vide page 18) about "Photographic Artists"! in which the term is ridiculed on the ground of Ruskin's definition of art, viz., "Human labour regulated by human design."

Now, the veriest tyro will agree as to there being plenty of the former in a photographer's work; but surely it is a fact that the latter is neglected to a large extent. Yet I venture to submit that, notwithstanding "faking" is a very ugly name, it does, and will, aid the photographer immensely in proving that his craft is an art after all; and, personally speaking, I like to

see the work of a man who is not only an "artistic photographer," but a "photographic artist" as well, for then he will not only choose and arrange his subject with artistic ability, but the resultant picture will have lost its mechanical or so-called "photographic" appearance.

The chief defects to be looked for in landscape negatives from the negative artist's point of view are:—Halation: Too much or too little intensity of lights or shadows; lack of clouds in landscape or through over-exposure of sky; moved figures and trees; undesirable loss of detail through haze; spots, light streaks from faulty dark slides; fog; imperfect lighting of subject, etc. All these defects can be more or less remedied by skilful handwork upon the negative. The order of such work should be: First, knife work; secondly, rubbing down; then fine pencil work on the medium film, and "splatter" work (if any). Then, after varnishing, stump pencil and brush work, matt varnishing on back, puttying, etc.

The knife will be chiefly required in removing specks, harsh lights on leaves, and for sharpening up moved figures. In doing the latter cut away the doubled outline on the denser portions,

t in with light touches such shadow detail which has  
arranged by the movement.

well, on commencing work, to decide concerning the  
of lights and shadows, and obliterate or subdue any  
irritating patches of light with the knife, or by rubbing  
The latter process (described recently in an article on  
etching Negatives of Interiors") will be used to remove  
lation, and to reduce hard lights and streaks of light  
g the negative through using a faulty dark slide. The  
is a very difficult thing to rectify, and whilst it is best  
rate upon the broader patches with alcohol and tripoli,  
narrower portions should be negotiated with a somewhat  
indiarubber charged with dry tripoli powder. However  
ly the streak may be removed, it is more than likely that  
amount of pencilling and stump work will be required  
afterwards to remove all trace of it.

Attacking hard lights full consideration must be paid  
ly to their intensity, but also to the range of gradation  
highest light to deepest shadow, and it is in little points  
ese that a dual knowledge of the art and science of photo-  
g manipulation becomes more fully necessary. For he  
be an artist who would retouch successfully a difficult  
ape negative, and, indeed, he must be more. He must  
photographer to understand just what to do, so that he  
es a "photographic artist," whether the "knights of the  
" like the term or not. The artist will, therefore, from  
points of view, allow his knowledge to direct him in  
ulating these masses of light and shade. After reduction  
en satisfactorily accomplished rub medium over the film,  
pon it pencil up all detail which needs strengthening,  
such matter as may be desired and conveniently produced  
pencils, which should be sharpened in two ways—a round  
oderately fine point, similar to that used for ordinary  
g purposes, and a flat-edged chisel-shaped one, the latter  
specially useful for putting in detail in foliage.

operate on the trees successfully observe their nature  
cally, and use the necessary form of touch to depict them,  
would in making a pencil drawing; only, remember you  
orking upon a negative, and not a positive. Sometimes  
ill find it convenient to use the broad and sometimes the  
w surface of the chisel-edge (pointing downwards) so as  
ble you to make broad or narrow touches. Approximately,

for oak, beech, and elm trees use the broad edge, and for fir,  
ash, chestnut, larch, pollard, willow, and yew use the knife-  
edge. Whilst probably the round-pointed pencil will be most  
serviceable in making the touches for birch, silver birch, weep-  
ing willow, and poplar trees.

### Splatter Work.

Splattering is a method of applying splashes of paint to  
lighten portions of a negative, or to represent shingle, stones,  
flowers, snow, etc. To apply, first lay the negative almost flat  
on a table, but inclining slightly towards the operator. Cover  
every part not requiring to be splattered with bits of paper.  
Then take a fine bristle nail or tooth brush, which, after being  
dampened, has been lightly charged with liquid indian ink,  
indian red, or "photopake." Then, holding the brush over  
against the negative, bring the teeth of a small-toothed nursery  
comb smartly over its surface in the direction of the operator,  
when a spray of splashes will migrate from the brush to the  
negative. When the work is applied over grass it will, with a  
little subsequent pencilling, give the appearance of flowers, of  
shingle if applied over paths or roads, or of waterweed and  
lilies over water. Some skill is needed to cause the smaller  
splashes to be deposited over the parts of the scene farthest away  
from the camera, and the larger ones in the foreground.

Before proceeding to varnish the negative it may be useful  
to knife in some herbage, water-reed, or water-ripples to com-  
plete the harmony of the scene. After varnishing with flattening  
varnish rub down and stump up the high-lights and shadows  
where necessary, finishing with pencil or brush work, and put-  
ting in lights over knifed portions, or, still further, working up  
trees and herbage so as to bring out from the rest of the subject  
such parts as seem (from an artistic standpoint) to need it.

When all has been done on the film it is seldom necessary  
to apply yellow putty or matt. varnish to the back of the nega-  
tive; but it is obvious that, should it be desirable, much addi-  
tional help can be rendered by such means.

I have said nothing about treating skies and putting in clouds,  
for this must be reserved for a future occasion.

In conclusion, it may be mentioned that many find actual  
brush work on the negative an additional and valuable aid in  
converting mechanical impressions into pictorial effects.

ARTHUR WHITING.

## BRITISH PICTORIALISTS THROUGH AMERICAN SPECTACLES.

isms, or, we suppose we ought to say, appreciations of the  
tions in the Little Galleries of the Photo-Secession occupy  
deal of space in our American contemporaries, where a remark-  
evolution is discernable. The scoffers now applaud and admit  
an almost surprising unanimity that Mr. Stieglitz has  
shed over all opponents, and though everyone may not see eye  
with him in art matters, no one questions the sincerity of his  
claim and the consummate skill with which he has organised  
public exhibitions of pictorial photography. In the "American  
our Photographer" we find a brief description of the present  
es in Fifth Avenue, in which the series of Secession Exhibitions  
ing held.

Little Galleries in New York consist of three rooms, all hung  
neutral burlap, and containing a few simple but effective  
ations of oak leaves and flower or grass sprays in vases. On  
alls the mounted prints are disposed in a single row under plates  
ss held in position by small tacks. The whole effect of extreme  
city sets off the pictures to great advantage.

he same issue of our contemporary appears a series of notes  
work of English pictorial workers who have shown in New

The opinions of the writer, "Roland Rood," will doubtless  
ad with interest if not with a certain amount of amusement  
udents of pictorial photography in this country:—

### J. Craig Annan.

The scientist is a man to whom nature does not speak. He must  
go to her, and with labour, cunning and infinite patience wrest from  
her her secrets. His function in life is dissecting and defining; his  
passion, discovery. When he has realised his passion and under-  
stands the nature of the cause or effect he has been searching for,  
his interest ceases and he turns in another direction. He is said  
to be inartistic in temperament; this is not so: he is merely un-  
artistic; and this as a necessary corollary to his composition. The  
artist is content to spend his life reiterating the same truth and in  
the end succeeds in doing it in such a way as to be generally intelli-  
gible and to charm; the scientist states each truth but once, and as  
his interest is absorbing knowledge for his self-satisfaction, he takes  
little pains in making his statement other than intelligible to him-  
self and a few of similar mind. When the scientist paints, his  
pictures, although all different from each other, and although all  
exemplifying some law, are uninteresting, because he has only  
appealed to himself. When, however, the scientist, in addition to  
the above repertoire of qualities, is possessed of penetrative imagina-  
tion, he becomes a most unusual being. Instead of having to attack  
nature bit by bit to read her, he is able almost intuitively to seize  
the truth, and, being an analyst, understand it when seized. He is

also able to understand human beings and thus explain the truth to them.

Such a man (the scientist with imagination) is J. Craig Annan, and his eighteen prints at present being exhibited at the Photo-Secession exemplify my definition. They are all different from each other, and literally almost seem the work of so many different men. To give a general description of their most characteristic traits is impossible; it would require eighteen different descriptions. As an exhibition, of course, such a combination is slightly distressing: no sooner is the visitor attuned to one mode of thought than he is thrown into another. The catalogue of the Photo-Secession speaks of Annan as being "one of the first of the living men to attract universal attention by the excellence of his work and by his spirit in the evolution of the photographic movement." And it adds: "He was one of the founders of the Linked Ring and is generally recognised as the strongest link in British photography."

**Frederick H. Evans.**

A sphere is a body every point of whose surface is at an equal distance from a point within called the centre. A sphere is at the same time the most perfect and the most incomplete of all bodies. It is the type of absolute symmetry, regularity and unity, but also of monotony. The conception of variation, rhythm and harmony cannot be attached to a sphere—only that of perfection. A sphere

has the advantage over all other bodies in that it is the most comprehended. Start out from any point on its surface, in any directions are alike. From any given point all the rays are identically the same as from any other point. The only difference in spheres is that some are larger and some are smaller.

Mr. Evans, honorary secretary of the Linked Ring, is a man of great artistic power. After having seen one of his thirty prints of architectural subjects, being now shown at the Photo-Secession, one has seen all the possibilities of the art. They vary from each other in size, it is true, but otherwise are the same. The subjects are all different, but the pictures are all perfect. They are all perfect. The exposures have all been exact, the developments equally exact. The printing likewise. Every detail, down to the minutest touch, is also perfect. All possibility of irregularity and consequent harmony has been eliminated. They are the result of the most deadly exact calculation, but such are incapable of arousing in the spectator any other feeling than that of admiration for their spherical perfection. For minutes I stood benumbed before them. More I cannot say, it is impossible to criticise perfection.

In conclusion I wish to congratulate Mr. Evans on his achievement, thought, ever circling around the centre, never receding, approaching, always returning on itself, logical perfection of physical expression.

## CERAMIC PHOTOGRAPHS.

LIKE many another beautiful process, the photographic enamel or ceramic has enjoyed but little popularity, and probably many of the younger generation have never worked one of the processes or even seen a specimen of the result. The recent publication (in translation) by Messrs. Liffé of a French work on the subject may draw attention to technical ceramic methods, though it seems a miniature of any kind cannot hope for any warm welcome just now. Nevertheless, it may be worth while to reproduce here, from our contemporary the "Photo Era" the directions for the iron "dusting-on" process, which has the advantage of others to which it is allied that the negative is printed from direct without the interposition of a positive transparency.

Of the many purposes to which photography can be applied the production of ceramic photographs is one of the most beautiful and, at the same time, one of the most useful. By its aid pictures of any colour or combination of colours can be produced on porcelain, and, by using suitable colours, also on glass. The objects to be decorated may be of any shape, although the photographs are most easily applied to flat or very slightly convex surfaces. It is evident that portraits, landscapes, and also exact copies of pictures can be reproduced in this manner. The process is eminently suitable for the production of miniatures.

### Ceramic Processes.

Ceramic photographs can be divided into two great classes, namely, those produced with ordinary pigments, as, for instance, by the carbon process (which, of course, cannot be vitrified and do not withstand the action of water), and those produced with ceramic colours, or with the precious metals, such as platinum, gold, etc., and which must be burned in. They are thus vitrified and become part of the ware. These pictures resist the action of all acids, except hydrofluoric, and also the action of the atmosphere, being, in fact, as permanent as the ware itself. The latter group can again be subdivided into two groups—i.e., the "substitution process" and the "dusting-on process." The "dusting-on process" can be carried out with (1) salts of chromic acid, (2) salts of iron. Of these processes, only the latter, employing salts of iron, will be described here.

This process possesses the advantage over the "dusting-on processes," employing salts of chromic acid, that a diapositive is not required, the printing being accomplished with the negative.

It is based on the fact that when a solution of ferric chloride of suitable strength is poured on a glass plate and dried in the dark a skin is formed, which is not hygroscopic. When this skin is exposed to sunlight the ferric chloride is reduced to ferrous

chloride by the action of the light. Since ferrous chloride is hygroscopic, it attracts moisture and becomes sticky, so that the ground powders will adhere to it. It is evident, since the ferric chloride is reduced by the action of the light and is thus rendered hygroscopic, that a negative must be used to print from. This is an advantage, because it saves the time and labour required to make a diapositive, necessary in the other "dusting-on processes."

### Iron Dusting-on Formulæ.

The chemicals required are cheap and readily obtainable. Several formulæ for preparing the solution, of which the sensitive solution is made, are in use. Of these, Poitevin's and Obernetter's will be given:—

Poitevin's Formula.			
Ferric chloride .....	10 gms.	154 grains	
Tartaric acid .....	5 gms.	77 grains	
Water .....	100 c.c.s.	3½ ounces	

Obernetter's Formula			
Iron citrate .....	10 gms.	154 grains	
Citric acid .....	5 gms.	77 grains	
Concentrated solution of ferric chloride .....	2 gms.	31 grains	
Water .....	100 c.c.s.	3½ ounces	

Dissolve the substances in the water; bring to a boil, cool, and filter.

After having carefully cleaned some glass plates (slightly larger than the required picture), and having prepared the solution according to one of the above formulæ, the process is carried out as follows:—

One of the clean glass plates is held in the left hand and a pool of the sensitive solution is poured on it, near the lower right-hand corner; the plate is then tilted, so that the pool spreads over the plate, being allowed to flow, first from the lower left-hand corner to the upper left-hand corner, thence to the upper right-hand corner, and finally to the lower right-hand corner. The excess is then allowed to run off the plate, at the lower right-hand corner into a clean bottle. This solution can be used again after filtering.

After the plate has been coated it may be put aside to dry spontaneously in the dark, or it can be dried by the aid of heat of a stove or over an alcohol flame, in a room illuminated by artificial light, or very diffused daylight. The two latter methods of drying are preferable.

### Printing.

When the plate is dry and while still warm it is put into the printing frame on the negative to be printed. Generally the film

of the prepared plate is placed in contact with the film side of the negative. By this method all the details of the negative are reproduced. If it is desired to produce broad, sketchy effects, the negative is reversed, so that the glass side of it is in contact with the film side of the sensitive plate. In order to produce the same effect a sheet of thin white tissue or tracing paper may be placed between the negative and the plate, but this method increases the time required for exposure.

The time of exposure varies, depending on the opacity of the negative and on the light. With a negative of medium opacity an exposure of about seven minutes in direct sunlight, or about one hour in good diffused daylight, is generally sufficient.

#### Development.

For development the plate is taken out of the print-frame and placed on a cold surface, where it is allowed to remain for several minutes. This treatment is specially recommended to be used in warm weather, in summer, and when the picture was printed in sunlight. For the development of the picture a small quantity of finely-ground ceramic powder colour, of the desired colour, is dusted on the plate and carefully spread, by a motion of a wide, soft brush. This must be done carefully, colour being added from time to time, as required. By this method the picture is slowly developed. When the process is complete—that is, when all the details are clearly visible—the excess colour is carefully brushed off the plate. If the plate was over-developed the development will be complete in about three minutes. It is well to remember that the picture becomes somewhat over-developed in firing and to develop it accordingly. If the plate is over-developed it develops too rapidly, and the colour also adheres to the plate; if under-exposed, the image will not take the colour properly—i.e., the colour will only adhere to those portions representing the deepest shadows. It is essential that the air of the

room in which the development is carried out is not entirely dry; it must contain a certain percentage of moisture. If, after removing the plate from the printing frame, it is breathed on, then the development can be carried out at once.

The picture being developed, it is fixed by pouring a 2 per cent. solution of plain collodion over it. The collodion is prepared by dissolving 2 parts by weight of gun-cotton in a mixture consisting of 50 parts by weight, each, of alcohol and ether. After the collodion has set, but before it has become dry, cut the film to the required size all around the picture with a penknife, and plunge the plate into a tray of water. This will loosen the collodion film, to which the picture is now attached, from the glass. The film is now carefully floated off the glass and washed out well.

The picture is now ready to be transferred to the object to be decorated. For this purpose the object is put into the tray of water containing the picture and the film carefully floated on, in the required position. With the aid of a soft brush this operation is easily carried out. Care must be taken to have the picture facing the right direction, and to avoid wrinkles. They can be smoothed out, by the careful use of the wet brush, as the object is lifted out of the water. This having been accomplished satisfactorily, the object is set aside to dry spontaneously. When thoroughly dry it is ready for firing.

Any of the ceramic powder colours on the market can be used, provided they are finely ground. For decorating porcelain, over-glaze porcelain powder colours must be used; for glass, glass powder colours. In regard to the choice of colours, it will be found that any of the blues, such as royal, delft, or old blue, produce good results. Deep red brown, which is more a brownish red, violet of iron, black, as well as the dark browns, such as chestnut, bitumen, Vandyke brown, and sepia also produce good results.

H. C. TER MEER.

## THE WAGES OF PHOTOGRAPHIC ASSISTANTS.

THE BRITISH JOURNAL OF PHOTOGRAPHY, dated September 3, 1897, set up a comparison between the general rate of wages of the years 1883-6 and 1897. During 1905 I compiled from the advertisement columns of the BRITISH JOURNAL OF PHOTOGRAPHY, and from information supplied by assistants and employers a record of the current rate of wages, and as this topic has recently been raised in the columns it may not be without interest to make a further comparison between the rates of the former periods, and those of the present time.

In my paper of 1897 the wages paid to assistants were divided into three classes, it being impossible to fix any uniform or standard wage. The average for these three classes worked out as under:—

#### COMPARISON OF WAGES 1883-6 AND 1897.—PER WEEK IN SHILLINGS.

	1883-1886.			1897.		
	1.	2.	3.	1.	2.	3.
Operator and Retoucher .....	70	60	30	60	35	25
Retoucher .....	84	60	40	60	40	35
Operator .....	35	30	25	63	30	20
Assistant Operator .....	30	25	20	30	25	18
General Assistant .....	80	25	20	30	25	22
Receptionist .....	80	25	21	35	30	25
Printer .....	18	15	10	30	25	10
Enlarger .....	50	—	—	50	40	25
Manager .....	—	—	—	16	15	10
Printer .....	—	—	—	18	12	—

The variation in rates between these two periods is not very marked; the chief differences being a fall in the wages of operators, and a rise in the wages of the first and second classes, and a decided rise in the wages made to a first-class receptionist. The other assistants remained in almost the same position.

Proceeding to the rates for 1905 my statement becomes as follows:—

#### WAGES IN 1905.—PER WEEK IN SHILLINGS.

	Rates by Assistants.			Rates by Employers.		
	1	2	3	1	2	3
Artist .....	65	60	55	100	70	60
Operator (Studio) .....	84	40	25	80	35	25
„ (Press) .....	60	—	—	60	30	20
„ (Commercial) .....	140	100	80	—	—	—
Operator and Retoucher .....	63	30	25	70	35	25
Retoucher .....	42	30	20	40	25	20
„ and B & W .....	50	30	25	30	25	—
Assistant Operator .....	50	30	20	30	25	21
General Assistant .....	45	25	20	40	25	18
Enlarger .....	42	—	25	—	—	—
Printer .....	35	25	21	30	25	20
„ (Bromide) .....	35	30	25	30	25	21
„ (Carbon) .....	35	—	—	63	42	—
Receptionist .....	80	25	6	—	—	—
Mounter and Spotter .....	18	14	10	15	—	—
Improver .....	21	15	10	18	15	10
Apprentice (Premium) .....	—	—	—	£75	£10	£40
Manager (Working) .....	50	40	25	35	30	25

These rates were collected, and averaged, without any consideration of the final result, and until they were tabulated it was not seen how closely the figures given by employers and assistants agreed. This would indicate that they may be relied on for accuracy. The standard of employers is quite up to that of the assistants, in several instances being much higher.

Compared with the table for 1883-6, and 1897, several important changes are noticeable. The list of workers has been extended to include those, now recognised as specialists, who, even in 1897, had no separate existence, i.e., the press operator, bromide printer, and others. This separation always follows the advance of any industry.

In the early stages one man will undertake a multiplicity of duties, but as the trade expands it becomes possible to divide these amongst several workers. New processes, and fresh applications of old methods also increase, and thus, in place of the all-round man, we have the studio, press, out-door, and commercial operators. The fact that such a division of duties has become necessary, is, in itself, evidence that photography has progressed since 1897.

Another point brought out is that the operator, artist, and every worker of special ability, are much better paid than in 1897, the rates being equal to, or more than, in 1883-6. An artist can now command a salary of £5, whereas, in the previous years, £2 10s. was considered enough. The operator in all departments has recovered the loss in wages which was evident in 1897 having now come back to the 1883-6 level. The photo-mechanical operator is at present the most highly paid of all photographic assistants, that is, if the figures given by assistants can be taken as a correct valuation of the rate accepted by employers. I do not think, however, that these high wages will be long maintained. During the last five years this branch has grown rapidly, and, in consequence, the number of men having a practical knowledge of the work is limited, the supply of experienced men not being equal to the demand. When things settle down these high rates can scarcely be paid by employers. The photo-mechanical operator thus occupies a unique position, hence his rate of pay cannot be taken as a standard for other workers in branches where the competition is more severe.

With the above exceptions the rate of wages shows but little movement since 1883-6. In the first class there is on the whole a marked advance, in the second and third a distinct fall. To assistants the moral of this comparison, extending over twenty years, is obvious. It proves beyond a doubt that good wages are regulated by the possession of special ability. It is quite useless to wait for the time to rise of their own accord, to depend on long service, or to expect an increase by reason of age and experience. What the assistant has to do is to increase his skill in order that he may rise from second and third class into the first. Once acquire this special ability and he becomes independent of the general rate of wages, and employers who are willing to engage his services at the highest rate.

Taking the seven chief workers in a photographic business, and summing up the value of their wages, per week, in 1905, it compares with the former periods as under:—

	1883-6.	1897.	1905.
Class I. ....	397 Shillings	308 Shillings	320 Shillings
" II. ....	240 "	210 "	195 "
" III. ....	166 "	155 "	145 "

Here again it is evident that the expert man is steadily improving his position, whilst the less skilled worker is as surely losing ground.

JOHN A. RANDALL.

## THE ACTION OF THE RELATIVE WEIGHTS OF ALKALI AND REDUCER.

THE experiments in the preceding paper (see p. 246) were repeated:—

1. With the same proportions of alkali (corresponding to 1.75 gm. of caustic lithia per litre) and with one-third the quantity of reducer and sulphite.

2. With the same proportion of alkali, and double the strength in reducer and sulphite.

3. With one-third the proportion of alkali and one-third the quantity of reducer and sulphite.

Under these conditions the numbers in the previous tables require some notable modifications.

With eikonogen, metol, paraphenyldiamine, metaquinone, metol and hydroquinone, par-amidophenol and adurol, the differences were found to be insignificant.

We have tested the reducing power of various developers containing equimolecular weights of the reducer with the addition of the same quantity of a caustic alkali—soda, for example. These developers have very different reducing powers.

We have recognised that it is possible to make with equimolecular weights of various reducers developers possessing the same energy, by adding variable quantities of caustic soda or carbonate of soda.

The necessary quantities of the alkalis to obtain this result are given in the following table:—

Names of the various developers in order of the decreasing reducing powers.	Equimolecular weights of the reducer in the like of developer containing 45 gms of anhydrous sulphite.	Caustic Soda.		Carbonate of Soda.	
		Relative weights of NaOH to produce the same reducing power. That for metoquinone being taken as unity.	Reducing power of the developers compared, glycidol being taken as unity.	Relative weights of Na <sub>2</sub> CO <sub>3</sub> to produce the same reducing power. That for metoquinone being taken as unity.	Reducing power of the various developers, glycine being taken as unity.
Metaquinone .....	12	1	4.2	1	74
Metol-hydroquinone .....	12	1.25	3.33	4	18.5
Paramidophenol .....	11	1.25	3.33	inc. sol. *	—
Paraphenyldiamine .....	11	1.66	2.5	spcl. case†	—
Hydramine .....	11	1.66	2.5	inc. sol. *	—
Picro .....	12.6	1.66	2.5	11	6.7
Hydroquinone .....	11	2.08	2	34	2.3
Picrocatechine .....	11	2.3	1.3	40	6.1
Metol .....	17	2.3	1.3	10	7.4
Eikonogen .....	26	2.3	1.3	11	6.7
Edinol .....	14	2.8	1.5	32	2.3
Adurol .....	14.5	3	1.43	17	4.1
Glycin .....	16.5	4.2	1	74	1

\* Incomplete solution.

† Special case.

An examination of this table enables us to draw the following conclusions:—

1. The caustic alkalis may be substituted one for the other, all developers, in equimolecular weights.

2. With the alkaline carbonates, not only are the quantities to be used much greater than the calculated equimolecular weights of the caustic alkalis, but also the various alkaline carbonates are not proportional to their own molecular weights.

Potassium carbonate, which has a greater molecular weight than the soda salt, must always be used weaker whilst the quantity of caustic potash to be used instead of soda must not be more. The proportions of alkaline carbonates are practically the same with the majority of developers, but notably differ with hydroquinone, picro, glycine, and paraphenyldiamine. Hydroquinone, the isomer of picrocatechine, requires about three times the quantity of alkaline carbonate that the latter does. Finally, glycine and paraphenyldiamine are exceptions to the rule. As regards the former we have already pointed out that less than 1 gm. of caustic soda to 2.5 gm. of glycine gives a very weak developing power, notably inferior to that obtained with the alkaline carbonates. Above this quantity the caustic alkalis are more active than the carbonates.

This anomaly may be explained by supposing that in glycine

the carboxyl is first converted into a salt by the caustic, and that the salt formed is not decomposed by hydrobromic acid, whereas carbonate of soda does not produce this salt in the cold, and can therefore act directly on the hydrobromic acid. If glycine is treated with carbonate of soda in the cold there is no evolution of carbonic acid. The quantity of caustic soda which exercises the normal reducing power is a little more than that required for salification. These facts support our hypothesis.

In the case of paraphenyldiamine these numbers are much higher and correspond to about thirty times the equimolecular weight, whilst with the caustic alkalis comparatively small quantities are sufficient. This anomaly may be explained by assuming that paraphenyldiamine, which is a strong base, absorbs the hydrobromic acid before it can decompose the carbonate of soda, and that the bromide formed is not decomposed in the cold by the alkaline carbonates, whilst it is by the caustic alkalis. In support of our hypothesis, it was found that the hydrobromide of paraphenyldiamine did not evolve carbonic acid in the cold in the presence of carbonate of soda.

With the alkaline substitutes different numbers are obtained,

which the greater number, those of trioxymethylene, aldehyde and tribasic phosphate, are about the equimolecular quantities calculated from the caustic alkalis.

Acetone gives very variable numbers, from 5 to 20 times the equimolecular weight, calculated from caustic soda. With certain developers, the reducing power diminishes considerably when a certain quantity of acetone is exceeded. The same phenomenon is observed with trioxymethylene.

In examining the experiments when only just enough alkali was used to neutralise the hydrobromic acid given off in developing a 13 x 18 plate, it was seen that this small quantity of alkali was sufficient to develop the latent image in an excess of hydroquinone; on the other hand it was quite insufficient if the weight of the hydroquinone corresponded exactly to the quantity of hydrogen necessary to form the hydrobromic acid set free. In this case a weak reducing action could be produced by considerably increasing the quantity of the alkali.

In examining the quantity of caustic alkali and alkaline carbonate which produced the maximum developing action for the various developers, it will be seen that the quantities are very different for the same proportions of reducers having equal molecular weights or nearly so, such as hydroquinone, pyrocatechine, par-amidophenol and paraphenyldiamine. These quantities of the alkalis differ notably, with the exception of hydroquinone, from those which can exactly saturate the hydrobromic acid formed with the hydrogen of the reducers, supposing that each molecule of the reducer furnishes  $H_2$ .

Finally, the preceding experiments prove that one can obtain the same reducing effect with equal molecular weights of different reducing agents, but by adding variable quantities of the same alkali, either caustic or carbonate, the order in which the reducers may be classified according to the increasing quantities of alkalis necessary to produce the same effect, differs considerably according to whether one uses the caustic or alkaline carbonates. In both cases it is metoquinone which requires the least and glycin which requires the most alkali.

This, then, is the order in which one may classify the various developers according to the increasing quantities of caustic alkalis which they require: Metoquinone, metol-hydroquinone, par-amidophenol, paraphenyldiamine, hydramine, pyro, hydroquinone, pyrocatechine, metol, eikonogen, edinol, adurol, and glycin.

To summarise, these different results prove that the alkalis or their substitutes play a role in development which is much more complex than is usually supposed. One cannot but admit, in fact, that a substance the purpose of which is primarily to saturate the hydrobromic acid set free in development by reduction of the silver bromide, cannot be replaced equimolecularly by different saturators of hydrobromic acid. At the same time one cannot deny that the reducers require variable quantities of the alkalis and their substitutes to produce the same reducing effect; these differences apply at the same time to two isomeric substances, such as hydroquinone and pyrocatechine, which the recent hypotheses do not explain more satisfactorily.

A. AND L. LUMIERE.

#### LENS-TESTING METHODS.

At the meeting of the Optical Society on March 29, at the Northampton Institute, Clerkenwell, Dr. Walmsley in the chair, Mr. S. D. Chalmers gave an interesting lecture on the subject of photographic lenses and their aberrations. The lecture was followed by a demonstration of the methods employed at the institute for determining these aberrations. Of these, two—one a visual and the other a photographic method—call for special notice.

In the visual method a special optical bench, designed by Messrs. Beck and Chalmers, is employed. In the original apparatus of Messrs. R. and J. Beck a lens-holder is adapted to slide along a steel rail some 50in. or 60in. in length. The same rail also carries a carriage upon which a second transverse rail is mounted. Upon this second rail an examining microscope is mounted to travel in a direction at right angles, of course, to the main rail. The lens to be tested is screwed into the holder, and the image of the test object produced by it is examined throughout a horizontal line extending through the image by means of the examining microscope, which is racked along the transverse bar for the purpose. In the modified apparatus employed at the Northampton Institute the

necessity for the transverse bar has been dispensed with in a very ingenious way. The lens-holder, as in the original form, is adapted to rotate about an axis passing through the back nodal point of the lens. The microscope which is mounted to slide in guides over and collinear with the main bar is so connected up to the lens-holder that when the latter is rotated it moves automatically along its slide the necessary amount to keep points in the ideal focal plane of the photographic lens in focus. The object to be observed is placed in the focal plane of a distant collimator. The apparatus is first adjusted so that the image of the distant point source, say, is projected on the axis of the photographic lens to be tested and in the centre of the field of the observing microscope. If the lens-holder be then slowly rotated, the image observed, if the aberrations present are of the usual kind, passes out, and it may be into focus again, and at the same time moves backwards and forwards in a horizontal direction in the field of view of the microscope. These longitudinal and transverse deviations can be measured with suitable scales for any inclination of the lens to the axis of the microscope.

The second or photographic method described by Mr. Chalmers is a modification of the well-known Hartmann method. The modification consists mainly in the application of graphic methods of analysis to the photographic results obtained. In the Hartmann method of lens-testing, as is well known, a perforated diaphragm is used with the lens to define a number of very small pencils, and then, by means of a photograph taken at various distances from the lens, the intersections of these pencils with a number of transverse planes are determined. From these photographs the path of each pencil is accurately determined with respect to three axes mutually at right angles to one another. Mr. Chalmers places the usual perforated diaphragm in the stop plane of the lens, and then, by means of a beam of parallel light, takes two photographs—one just within and the other the same distance without the focus of the lens. In the case of an ideal lens these two photographs, after one had been rotated through an angle of 180deg. in its own plane, would exactly superpose the discs or dots on one on those of the other. When, however, as is usually the case, some of these pencils defined by the perforations in the diaphragm, do not intersect in the focal plane, this superposition becomes impossible, and the measure of this departure from superposition is a measure of the aberration of the lens. This superposition is effected graphically in the following way: One of the photographs is placed on the object stage of a microscope and its magnified image projected by means of a camera lucida on to a sheet of paper, upon which dots are made corresponding to the positions of the small discs in the image. The second photographic plate, after having been properly oriented on the stage of the microscope, is then treated in the same way and its image superposed, so far as possible, and drawn on that of the first plate. The second series of points obtained may be differentiated from those of the first by means of small crosses. In this way magnified images of the two photographs are superposed, and the distance between corresponding points becomes a measure of the aberration. Pairs of photographs are taken and treated in this way for inclinations of the incident beam of 0, 5, and 10 degrees, etc.

#### DEVICE FOR DEVELOPING CORONA PHOTOGRAPHS.

ONE of the great difficulties encountered in photographing the solar corona during total solar eclipses (writes Mr. C. P. Butler in "Knowledge") is caused by the very great range in intensity of the object; in most cases it is necessary to expose many different plates for carefully arranged times of graduated duration, so that we may obtain records of all parts, from the intense inner corona to the delicate tracery of the outer streamers. If a photograph exposed for any considerable time is developed normally the inner corona is generally so dense by the time the outer details are brought out that it is unprintable.

Numerous suggestions have been brought forward for getting over this difficulty, the most successful hitherto being that of Burckhalter, who arranged a carefully calculated series of rotating screens over his photographic plates during exposure, so that the outer regions received more than the inner parts. These were partly successful in that all parts of the corona could be obtained of printing density

on the same negative, but the artificial lines produced by the occulting screens were objectionable. Recently a method has been proposed by Mr. T. Thorpe, which appears to give promise of success. Instead of developing the negative in the ordinary way, it may be mounted on a turntable, and centred so that the centre of the corona is coincident with the axis of rotation. Then by means of a small funnel or pipette mounted on a radial arm also working on the same centre as the plate, begin the development by allowing the developer to fall near the edges of the plate; afterwards gradually approach the stream of developer from the funnel towards the centre, restraining the developer also if found necessary, as it approaches the over-exposed parts of the inner corona. The centrifugal action due to the rotation of the photographic plate will, of course, prevent any of the developer getting nearer the centre than is desired.

### TACT IN LETTER WRITING.

CONVINCING letters being now part of the machinery of almost every business, the art of writing the right kind of letter is one which men of business must cultivate if they cannot afford to employ a professional for the purpose. It may be to the advantage of some readers if we give a few hints from the current issue of the "Business Man's Magazine," which reaches us for review filled with a series of articles treating of many diverse business themes:—

A good letter makes a sharp impression at the right place and at the right time. A bad letter lessens the impression which may have been created by a first and stronger one. Two weak letters following one strong one will make no impression whatever.

This is what Mr. Cody says:

"Write a long letter to

"A farmer.

"A woman.

"A customer who has asked you a question.

"A customer who is angry and needs quieting down, and will be made only more angry if you seem to slight him.

"A man who is interested but must be convinced before he will buy your goods.

"Write a short letter to

"A busy business man.

"An indifferent man on whom you want to make a sharp impression.

"A person who has written you about a trivial matter for which he cares little.

"A man who wants only a record of a piece of information.

"A person who needs only the slightest reminder of something he has forgotten or overlooked."

### FORTHCOMING EXHIBITIONS.

March 31 to April 10.—Salon of the Photo Club of Nice. Address the Secrétaire-Général, 20, Rue St. Francois de Paule, Nice.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 2 to 7.—Photographic Society of Ireland. Secretary, W. F. Cooper, 194, Clonliffe Road, Drumcondra, Dublin.

April 16-21.—Redcar Photographic Society. Entries close April 9. Secretaries, W. H. Taylor, Esplanade, and J. M. B. James, 4, Elton Street, Redcar.

April 18 to 20.—Southend-on-Sea exhibition. Hon. Sec., J. Archer, 24, Ashburnham Road.

April 18 to 21.—Bolton Amateur Photographic Society. Secretary, T. W. Cross, 27, Latham Street, Bolton.

April 20-21, 1906.—Watford Photographic Society. Hon. Secretary, C. J. Trevanthen, Ashcroft, Bushey Hall Road, Watford.

April 27-May 27.—Northern Exhibition (Manchester). Sec., G. M. Morris, 9, Chandos Road, Chelton-cum-Hardy, Manchester.

May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

## Exhibitions.

### WORTHING CAMERA CLUB.

THE Worthing Camera Club held their first annual exhibition on March 27 and 28, at the Bedford Hall, Worthing, the event proving a greater success than could have been anticipated. Members in particular showed up well, both in regard to number of exhibits and quality of the work: There were upwards of 300 exhibits in all classes. In the open classes eighty-three were frames, and amongst the chief exhibitors were the following:—V. E. Morris, Fred Judge, W. Clayden, Miss Sylvia Cardwell, T. R. Somerford, F. J. Phillips, A. R. Sargeant, Miss K. Smith, W. Farren, Colonel Johnstone, W. W. Palmer, W. A. Walburn, S. G. Kimber, Graystone-Bird, and H. Wormleighton. Fred Judge was represented by three landscapes, all of remarkably good quality, and must have run the winners very close. He took first award for slides. W. Clayden showed his two well-known exhibits, "A Glean of Light," and "Tugging Home," and the former took a bronze plaque. S. G. Kimber was represented by five or six frames, and took chief award—a silver plaque—for one of his well-known architectural studies, and also an hon. mention for his "Riverside Reeds." A. R. Sargeant was represented by two seascapes, both of which have been hung at the Royal. He obtained a bronze plaque for "A Calm Evening." William Farren had both prints and slides of his natural history work. In the Members' Classes Mr. H. Swain took a bronze plaque with the print entitled "The Anglers." No. 132, "Summer," by Mr. W. A. White, was a very nice little woodland scene which was distinctly meritorious in every way, with the plains receding well, and the distance well expressed. This secured the second award. A bronze medal went to Mr. R. Long for No. 114, "When the Sun is Low," a special feature of which was the remarkably soft sky and the true tone value. Mr. Woodward took a medal for "The Breaking Waves Dashed High," No. 120. No. 229, "Mother's Sunshine," by Mr. E. F. H. Crouch, was of purely domestic interest. It, however, represented a child in a very engaging attitude, and the technique was decidedly good. Very different from the one with which Mr. Walter Gardiner gained an award was his No. 225, "Happy Moments," which was an artistic rendering of an old man's head, capably lit, and quite convincing. Mr. W. A. White was awarded the silver plaque for the best three exhibits in the members' class. The loan section was also well represented. Three well-known pictures by A. Horsley Hinton, two by Charles Job, and another by the late H. P. Robinson standing out in prominence. An interesting feature in connection with the exhibition was the excellent illustrated lectures, "Winchester Cathedral," by S. G. Kimber; "Homelife in Birdland," by O. G. Pike, and "Morocco," by A. H. White who also gave practical demonstrations with the aerograph each day.

### WEST SURREY PHOTOGRAPHIC SOCIETY.

THE eighteenth annual exhibition of this Society was held from March 28 to 31 last. The hanging of the pictures had been carried out with much taste and judgment under the direction of Messrs. W. Calder Marshall and H. Creighton Beckett, of the "South London," and a good deal of original and striking work was to be seen. The judge was Mr. A. Horsley Hinton, who made the following awards:—Silver plaque for best picture in exhibition, "A Drifting Mist," by W. G. Rouse. Class I. (pictures by members who have received awards at this Society's exhibitions during the last three years):—Bronze plaque, "Chrysanthemums," by W. H. Goy; bronze plaque, "Old Westminster," by A. Lockett; honourable mention, Mrs. W. H. Goy, V. Nichols, and Dr. H. Pelham Webb. Class II. (pictures by all other members):—Bronze plaque, "When the Day is Done," by B. Gilbert; bronze plaque, "The Bridge," by W. H. Wilshire; honourable mention, F. J. Toms, R. H. Baskett, B. Gilbert, and F. J. White. Lantern slides:—Bronze plaque, "Tugging Out," by F. G. Tryhorn; honourable mention, C. A. Clear, G. W. Coleman, W. H. Goy, and A. H. Butterworth.

## PHOTOGRAPHIC SOCIETY OF IRELAND.

THE annual exhibition was opened on Monday, April 2. The hon. secretary, Mr. Cooper, is to be congratulated on securing a good show. The "Werner" medal is carried off by Mr. Harold Jacob for his "Cathedral Door," a very broad, soft picture, with a good effect of sunshine. The same print also takes the silver medal in the landscape class. Mrs. Mahony takes a bronze medal for a "City Highway," a picturesque view of the Liffey and Custom House. The Rev. E. Vernon Hanson has several dainty landscapes and seascapes, but the titles of the prints in bright white letters on dark mounts are rather distracting. "The Lovers' Walk" is commended.

The Portrait Class is rather weak, as the negatives must not be taken in a professional studio. The silver medal is awarded to Mrs. Mahony for "Hurry and Leisure," a little boy digging in the sand, while a train puffs away in the distance. Mr. A. Ponton takes the bronze medal for a pretty portrait of a "Dutch Fisher Girl."

The Architecture Class is not large, but there is some good work in it, especially Mr. J. B. Anderson's "The Old Pulpit, Lichfield Cathedral," which would, however, be improved by being a little more vigorous.

In the Still Life Class, which is rather a small one, Mrs. Frank Perry takes the bronze medal for a very good photograph of "Poppies," but a great mistake is made in printing in a dull, unpleasant green. It is strange how many good negatives are spoiled by printing in unsuitable colours.

In the Open Class the gold medal was withheld as there were less than one hundred entries. Mr. Arthur Marshall's "Dusty Day" well deserves the silver medal it receives. Mr. Fred Judge secures the bronze for a strong cloud effect over a picturesque church tower, entitled "October." "Through a Courtway," a very bright, delicate street view by A. W. Walburn, receives an extra bronze medal. "Sunshine," by Mr. Thomas Clarke, is commended. It is a capital rendering of sunshine glinting down a rough, whitewashed wall, but it would be greatly improved by reducing the strength of the cast shadow of the little girl standing in the roadway. The best architectural work was shown in the Lantern Slide Class.

The Society would be able to make even a better exhibition if some of the other good workers would support the Hon. Secretary in his efforts to secure a really representative show of Irish work. This year the Society tried the experiment of having only one judge, Mr. Harold Baker. The following is the award list:—

LIST OF AWARDS (Members' Classes).—Class 1.—Landscapes, etc.—Silver, Harold Jacob, No. 2; bronze, Mrs. Mahony, No. 28; Commended, Rev. E. Vernon Hanson, No. 32; Werner medal, Harold Jacob, No. 2. Class 2—Portraits, etc.—Silver, Mrs. Mahony, No. 64; bronze, A. Ponton, No. 65; commended, Mrs. F. Perry, No. 63. Class 3—Architecture.—Silver, J. B. Anderson, No. 101; bronze, T. K. Hackett, No. 97. Class 4—Still Life, etc.—Bronze, Mrs. F. Perry, No. 110. Class 5a—Lantern Slides.—Silver, J. B. Anderson; bronze, H. Pollock. Class 5b—Lantern Slides.—Silver, H. Pollock; bronze, J. B. Anderson. Class 6.—Bronze, Mrs. Sutherland, No. 121. Class 8—Open.—Silver, A. Marshall, No. 162; bronze, Fred. Judge, No. 148; bronze (extra), A. W. Walburn, No. 137; commended, Wm. Clayden, No. 160; commended, Thos. Clarke, No. 139. Class 9—Open.—Silver, W. F. Caldwell, No. 170; bronze, R. Douglas Percival, No. 193. Class 10—Open. Lantern Slides.—Silver, F. G. Tryhorn; bronze, Fred. Judge.

CHEMISTRY in Germany.—Not content with their handsomely endowed schools of chemistry, the Germans are proposing an Imperial Chemical Institute. A large number of representatives of chemical science and of the chemical industry met recently in Berlin to discuss its formation and organization. The chair was taken by Professor Fischer, of Berlin University, who explained how urgently an Imperial Chemical Institute was needed, for neither individuals, nor the University laboratories, nor the laboratories attached to chemical factories were able to solve the great questions that had arisen in the ever-extending field occupied by chemistry. It is estimated that the initial cost of such an Imperial Chemical Institute would be between £100,000 and £150,000, and the annual expenses about £20,000. It is hoped to get financial aid for the project from the Imperial funds.

## Photo-Mechanical Notes.

## Photographing Chinese and Process Whites.

IN the "Photo-Engravers' Monthly" for April, there is an article dealing with this subject, and reproductions showing the difficulty met with by blockmakers when having to handle originals with unsuitable whites. The remedy is pointed out, and consists in the use of a filter of 10 per cent. quinine sulphate. This is stated to make the exposure on ordinary wet plate with enclosed arc lamps three times as long, some enclosed arcs we should imagine may require more, but with open type arc lamps we have found the exposure required to be not more than twice normal. If a dry filter is required, instead of the liquid quinine sulphate, it may be made in the same way as a gelatine colour filter is usually made, taking a saturated solution of Aesculin for the dye, in which the gelatine coated plate is bathed. This will increase the exposure slightly more than the quinine sulphate.

## Process Advertising.

Other firms are following the example set by one or two of the bigger concerns in sending printed matter direct to customers. The Marshall Engraving Company are sending out a large post card containing portraits of the proprietors and the principal men of their staff. The small blocks are effective enough, but the arrangement of the type matter is just a little distracting, and smooth-surfaced cards of the character used are very liable to be damaged in the post.

## Etching Plates.

According to Patent No. 4,764, 1905, the object of a new invention is to etch zinc or other metal plates expeditiously, and so as to produce the maximum sharpness and clearness of the design—further, to subject the plate to a scouring action during etching, and also so as to allow of the inspection of the progress of the work. The plate is placed face upwards, and the etching fluid is allowed to fall on to the face in the form of a rain. Fig. 1 shows a suitable apparatus in

Fig. 1.

Fig. 2.

which the etching fluid is in the tank at the top, and the plate in the trough at the bottom. The etching fluid can be pumped from the trough to the tank if necessary. Fig. 2 is the enlarged vertical

section of a part of the plate showing the action of the fluid in striking the same. The drops strike the plate with such force and velocity that the deposits formed by the etching fluid are dislodged by the impact of the fluid and the splashing and scouring action due to the rebound completes the separation of the fluid and washes it away. The invention is said to etch all parts equally, and to involve less danger of over-etching small details or lines. William Gardner Thorpe, 30, South Broadway, Los Angeles, California, U.S.A.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between March 19 and 24:—

**CINEMATOPHGRAPHS.**—No. 6,625. An improved device effecting a greater efficiency of light in relation to the periods of rest and movement in changing cinematographic views mechanically. George Robson, "Oowana," Stour Road, Bournemouth.

**COLOUR-PHOTOGRAPHY.**—No. 6,825. Improvements in diffraction colour-photographs and mode of making same. Herbert Eugene Ives, 47, Lincoln's Inn Fields, London. [Date applied for under Patents Act, 1901, 19th October, 1905, being date of application in United States.]

**OPTICAL SCREENS.**—No. 6,881. Improvements in optical screens for photographic and printing purposes. John Henry Smith, 65, Chancery Lane. [Date applied for under Patents Act, 1901, 23rd March, 1905, being date of application in Germany.]

**CHANGING FILMS, ETC.**—No. 6,291. Improvements in the method and apparatus for changing films, plates, or the like, in photographic cameras. Optische Anstalt C. P. Goerz Akt. Ges., 31, Bedford Street, Strand, London. [Dated applied for under Patents Act, 1901, 27th March, 1905, being date of application in Germany.]

**LOCATING DEVICE.**—No. 6,970. A device for finding the location of objects and places on photographs, views, and other pictorial representations without defacing the same. Reginald William Giliard, 22, Redcliff Street, Bristol.

**DEVELOPING APPARATUS.**—No. 7,012. Improvements in photographic developing apparatus. William Albert Edwards and Houghton's Limited, 88, High Holborn, London.

**POSTAL WRAPPER.**—No. 7,019. An improved postal wrapper for photographs and the like. Louis Canesi, 9, Warwick Court, Gray's Inn, London.

**WASHING APPARATUS.**—No. 7,057. Improved apparatus for washing photographic prints, papers, films, and the like. Edgar Marsh Chapman, 56, Ludgate Hill, London.

**CAMERAS.**—No. 7,099. Improvements connected with photographic cameras. William James Lancaster, 11, Burlington Chambers, New Street, Birmingham.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**REDUCERS.**—No. 6,276, 1905. The invention relates to reducing agents with selective action. The claim is for a photographic reducing agent, the use of salts containing cobalt, the nitrite radicle group ( $\text{NO}_2$ ), and potassium, sodium, ammonium or other metals, with or without other acid radicles, in conjunction with an acid such as sulphuric acid. A modified-form of the reducing agent wherein potassium nitrite, sodium nitrite or the like, and a cobalt salt, with or without a salt of ammonium or the like, are used in conjunction with an acid. The use, in conjunction with a cobaltic reducing agent of the type hereinbefore set forth, of a bath of dilute ammonia for the purpose of preventing discolouration or change of colour of the image after the reduction. Harry Edmund Smith, 3, Ezra Buildings, Columbia Road, London.

## New Books.

"Die Photographische Kunst in Jahre," 1905. Halle. W. Knapp, M. 8.

This yearly review of pictorial photography continues to appear, under the editorship of F. Matthies Masuren, whose policy we can heartily approve, in so far as he does not inflict criticism of the photographs upon us, but does his best in the way of reproduction and leaves us to take the work for what it seems worth. Naturally German and Austrian work occupy a large place in its pages, but not sufficiently so to rob the volume of its claim to be international. Practically all schools and countries are represented, either by half-tone reproduction in the text or separate plate illustrations. Such men as Kühn, Henneberg, Dr. Spitzer, Dürhkoop, and Eckhardt figure largely, but the pictorial photography outside Germany is very amply shown by Demachy, Coburn, George Davison, Fredk. H. Evans, Mrs. Coltani, and a number of others. The text is composed of several essays on art topics, an appreciation of some exponents of British pictorial photography, by E. O. Hoppe, and notes on the exhibitions, English and foreign, of the year. The pictorial portion, however, is the *raison d'être* of the volume, and in selection and execution is a work on which the author may be warmly congratulated.

"Vorlesungen über Photographische Optik." By Dr. Alexander Gleichen. Leipzig: G. I. Göschen. Price, 9 m.

This work is practically a series of lectures delivered by the author at the Technical High School of Charlottenburg. Starting with purely elementary definitions, the formation of images is considered, and then the various aberrations discussed: all the mathematical formulæ which enable them to be corrected being given. Some brief historical notes of the details of construction, such as radii of curvature and separation of some lenses, are also included, and the book concludes with some examples of lens calculations.

An invaluable volume to the prospective resident in London has been published by the Homeland Association, Ltd. It is "Where to Live Round London," and describes ninety residential districts to the south and west of London, giving in each case particulars of local rates, price of gas, educational, recreative and railway facilities, and other data which should guide not only the home-seeker but those who contemplate establishing themselves in a district for business purposes. The price of the volume is 1s., and it is to be followed in a few weeks by a companion work dealing with the northern side of the metropolis.

The literary series of the "Practical Photographer," which reaches its thirtieth number with the March issue, is to be published in future at intervals, to be subsequently announced. Its regular monthly appearance is to be replaced by that of what is virtually a new periodical, "The Practical and Pictorial Photographer." This latest form of the "Practical" is to be double the superficial size of the Library Series, and to cost the same—viz., 1s.

We have received the latest handbook of the Homeland Association, which is a guide to the beautiful and interesting county town of Dorset, immortalized by Mr. Thomas Hardy as "Casterbridge," and the centre of the country in which the scenes of many of Hardy's novels are laid. The guide treats fully of the Literary and Archaeological Association of Dorchester.

**EMOLLIENT for the Hands.**—A writer to the "Pharmaceutical Journal" recommends the following preparation for leaving the hands neither sticky nor greasy. It is made in two solutions:—1. Agar-agar, 80 grains; distilled water, 8 fl. ounces; solution of hamamelis, 12 fl. ounces. Allow to stand a few days, with occasional stirring until dissolved, then strain through muslin. 2. Stearin, 360 grains; oil of theobroma, 360 grains; sodium carbonate, 240 grains; distilled water, 12 fl. ounces. Heat these together in a water-bath, stir until chemical action ceases, then transfer into a large jar, and whip up thoroughly with No. 1 solution with an egg-whisk, or in an emulsion machine, until a white, foamy product, and the whole is incorporated. Add perfume *q.s.* Allow to stand fourteen days for air-bubbles to subside, then bottle in wide-mouth screw-cap bottles.

## New Apparatus, &c.

A NEW electric dark-room lamp has been placed on the market by Messrs. A. E. Staley and Co., 19, Thavies Inn, E.C., fitted with the silk light-filters of Dr. Miethe, which we were recently able to review favourably in these columns. The lamp is of square build and carries a light filter in front and on each side, the series providing ruby, yellow, and orange lights, each and all of which can be perfectly shut off by a metal shutter. The lantern is fitted with two incandescent lamps, one inside and one out, and by the movement of a switch on the top of the body the light is transferred from one to the other. White light at will being always a convenience in the dark-room, this accessory should enhance the value of what is apart from it a very convenient and efficient lantern for all kinds of work. The price complete, with three silk filters and ground glass screens, 8 x 6 inches, two lamps, and flexible connection, is £22s.

THE "Renaud" Quick Bromide Printer, made by Messrs. Marion and Co., and recently noticed in these columns on its first introduction, is now issued in two larger sizes, viz., to print from 12 x 10 negatives downwards, price 60s., and from 15 x 12 negatives downwards, 70s. The details of these large size printers are the same save that they are fitted for two incandescent electric lamps instead of one.

A NEW pattern of postcard album reaches our table from Messrs. John Walker and Company, Ltd., Warwick Lane, London, E.C. It consists of a single stout board enclosed in a cover. To each side of the board are attached 13 gummed slips, each of which secures one postcard in place on the moistened edge of the card being pressed upon it. The effect of this arrangement is that the 26 cards occupy the superficial space of four, and yet each is most easily accessible. The album is a highly convenient one, not only for postcard collectors, but for professional photographers desiring to keep at hand specimen sets of their series of cards. The albums, which are attractive in appearance, sell retail at 6d. each.

### CATALOGUES AND TRADE NOTICES.

A SALE is being held by J. J. Griffin and Sons, Limited, at 20-26, Sardinia Street, Lincoln's Inn Fields, prior to their removal to their new building in Kingsway. They have determined to dispose of the whole of their camera and accessories stock, much of which is of 1905 pattern, at very large reductions on the original prices, and for those who like to take advantage of the chance, they are offering special inducements in the shape of the following offers:—Any amateur depositing with them the value of the instrument will receive the same carriage paid, on sale or return for three days. If then he is dissatisfied with his purchase the camera may be returned and the money will be refunded. Any amateur making the necessary application can examine any camera he may select at the local dealer's. All that is necessary in this case is to write to Messrs. Griffin stating what camera is chosen, and the name of the usual dealer, when the camera will be sent down without any charge for carriage. A list of the goods may be obtained upon application, and it is a chance which will be welcomed by many.

MRS. H. P. Ashman, of Bath, advises us that after the 31st inst. her business will be taken over by Mr. Percy Hooper Jones, who will trade as W. Middleton Ashman and Co.

MESSRS. Salmon and Sons, the enlargers, announce their removal from High Street, Acton, to premises at 52, Mattock Lane, Ealing, W., capable of accommodating their increased staff. Messrs. Salmon also submit to us a selection of enlargements representing their regular work, and representing it, we find, to very good advantage. We must especially commend the sepia-toned bromides, which are exceedingly rich in depth and colour.

A SPRING sale which should offer exceptional opportunities for the purchase of apparatus is that of the Stereoscopic Company, which is selling out its stock at 34, Cheapside, to make room for structural alterations of the premises. A line to them will bring the catalogue of the sale.

PROFESSIONAL photographers and photographic dealers who set a proper value on effective window display should make a point of examining the collection of prints on Paget papers which occupies one of Messrs. Houghton's windows in Holborn. Apart from the excellence of the prints, which may be taken for granted, their display is worth study. They are arranged on a four-fold screen of blue-grey arras cloth mounted as a panel in dark wood framing, which is suitably decorated and inscribed. The whole production, which we learn was the work of Messrs. Rogers and Webster, cannot cost very much, and is handsome without appearing gaudy, or in bad taste.

MESSRS. B. J. Edwards and Co. advise us that Mr. J. B. Pettet will in future represent them in the South of England below Northampton.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
6.....	Aberdeen Amat. Photo. Assn.	{ Last Season's Holiday Pictures (Lantern).
6.....	Sutton Photographic Club .....	{ "Enlarging on Bromide." Mr. C. Thwaites.
7.....	North Middlesex Photo. Soc. ...	{ Trip to Hoddesdon.
7.....	Chelsea and District Ph. Soc. ...	{ Excursion to Ruislip.

12.....	Darwen Photographic Assn.....	{ "What Can be Done with a Hand Camera." (Goerz Lecture).

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held March 3, the president, Major-General Waterhouse, in the chair. A demonstration of three-colour printing on the auto-type trichrome tissues was given by Messrs. H. J. Burton and A. C. Braham, of the Autotype Company. Mr. Braham, in accompaniment of Mr. Burton's demonstrative share in the proceedings, said that the process of building up three-colour prints by the process could not be called rapid, but to those who were accustomed to the double transfer process it was not difficult. As temporary support the company preferred a good post paper with the usual lac coating and waxed. It was better than celluloid, although not so transparent, as there was no need to squeegee the tissue to it, and therefore the chances of distortion were much less. They found that

when wetted the tissue expanded equally, and gave no trouble as regards registration. For the final support they used the ordinary single transfer paper. In printing, the use of the usual actinometer was not advised. The light was best tested with a rapid actinometer, and the exposures given in accordance with previous experience and in reference to the colour of the tissue. It would be found that the yellow image was plainly visible, the blue slightly so, and the red not at all. The demonstrators gave the necessary formulae for transferring and washing, in place of repeating which we may refer our readers to the description of the process by Mr. Burton in the "B.J." of February 9 last. The operations involved in the process were each shown by Mr. Burton, and the whole series of stages in the making of the carbon trichrome demonstrated by starting afresh on prints prepared beforehand. The demonstration was thus the model of what such an event should be.

Major-General Waterhouse, in proposing a vote of thanks to Messrs. Burton and Braham and to the Autotype Company, alluded to the progress in three-colour photography as evidenced in the recent exhibition at THE BRITISH JOURNAL OF PHOTOGRAPHY and compared the modern practice with his early efforts of thirty years ago.

**BOWES PARK PHOTOGRAPHIC SOCIETY.**—On Monday evening, 2nd inst., Mr. John H. Avery lectured on "Toning Bromide Prints." Speaking of exposing bromide paper, Mr. Avery advocated that printing should be done by candle light, as it was always constant, and when once the correct exposure was found, results could be duplicated with certainty. It is advisable to have a board marked off in divisions of one inch, a candle is placed at one end, and the printing-frame is placed at a distance equivalent to the length of the plate, e.g., for 5 x 4.5 inches, 10 x 8.10 inches, and so on. Mr. Avery said that in his opinion amidol was undoubtedly the best developer for bromide paper, and it was most simple in formula. An amidol developer should never be made up in the dark room, as particles of the dry chemical would float about in the air, and probably cause black spots on the developed print. In using a sulphide toning bath it is always better to boil the sulphide before making the bath, to get rid of any iron, which would eventually cause spots on the toned print. Prints should always be immersed in the toning bath in a dry condition, as the resulting tone is then richer. Mr. Avery also recommended the sulphide bath for toning lantern slides, and stated that by using different developers for the slides, so as to get various grades of black, and altering the amount of bromide of potassium in the toning bath, one can get a variety of tones in the finished slide ranging from dark brown to brilliant red. With a slide developed with pyro-ammonia and developed to a green-black, the result would be a bright red, if the amount of bromide in the toning bath be increased to 2,000 grains in 10 oz. of water. Mr. Avery concluded his lecture by showing an excellent collection of his "Morocco" slides.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting on the 29th ult. (Mr. Teape in the chair), Mr. W. R. Stretton delivered a lecture, which he entitled "Photographic Sketching." He said:—My own idea when I took up photography was to use the camera for sketching, pure and simple, an idea greatly modified upon finding that before results would even approximate to my requirements, the study of many regulating conditions was necessary. Mr. Stretton showed a series of excellent slides illustrating the use of the camera from the sketching point of view; the series including byways and nooks in the country, river, and coast scenes; and during his remarks he alluded to the indiscriminate use of morning and evening sky effects, and said that it seemed to be the idea that any sort of sky would do, irrespective of direction or attitude of the sun, and a complete disregard seemed to be made of the fact that the light of the heavens dominated the earth, and it was simply preposterous to produce pictures that showed the contrary. He preferred to use a narrow angle of view. He used lenses of 6 and 9-inch focal length on a quarter-plate, and 9, 12, or 18-inch on a half-plate, but most of the exposures were made with lenses of 9 inches and upwards.

**NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.**—On March 28, Mr. J. C. S. Mummery, F.R.P.S., gave a lecture and demonstration of gum bichromate. There was a very large audience of members and friends, which would seem to prove that the interest taken in this

process is greatly on the increase. Mr. Mummery mentioned that the process was a very old one, having been originated in 1858 by Mr. Pouncy, of Dorchester, but though Mr. Pouncy was able to produce some very fair results, many of those who tried it at that time failed hopelessly, and in a short time it fell into disuse. It was only about 1894 that it was unearthed, and since then, as its great possibilities for pictorial work have become realised, it has come into increasing and general use. The lecturer explained that there were two methods of working the process—single coating and multiple coating, but he said that, in the hands of skilful workers, there was little to choose between them, though in the single-coating method it was more essential to have a good negative, with just the correct scale of tones. The lecturer proceeded to demonstrate practically the multiple-coating method. He showed how the paper was coated, using a mixture of 54 grains ivory black, 1 ounce 40 per cent gum solution, and 1 ounce saturated bichromate of potash solution. He then developed, by means of a spray diffuser, a print in which the result aimed at was obtained in two coatings. For the purposes of demonstration, two prints of the same subject were used. One showed the result of the first printing, and the other the second printing. In practical work, of course, after the first printing had been developed, the same piece of paper would be recoated and printed on again, in accurate register with the previous printing. Mr. Mummery showed samples of several papers suitable for the process. A good deal of his own work was done on the O.W. Paper and Arts Co.'s machine-made paper. Readers of the B.J. who would like to join the North Middlesex will be cordially welcomed at any of their meetings, which are held every Wednesday, at 8.15, at Hanley Hall, Sparsholt Road, Crouch Hill.

**AT CLEVELAND LITERARY AND PHILOSOPHICAL SOCIETY** at Middlesbrough last week, Mr. Harold Hood delivered an interesting and instructive lecture on the subject of "Photography Applied to Journalism."

**TUNSTALL AND DISTRICT PHOTOGRAPHIC SOCIETY.**—On March 28 Messrs. E. B. Wain and J. R. Capey demonstrated to their fellow members the new "Page Croft Pigment Paper." The simplicity of working and beauty of results caused much comment. The delicate detail obtainable at will was much admired, and contrasted greatly with some of the splodges previously known as gum prints.

**WATFORD CAMERA CLUB.**—At a meeting on March 22, Mr. E. Seymour gave a lecture on the subject of "Printing Processes." He specially dealt with the subject of gaslight or slow bromide papers, which, as is well known, he largely uses in the production of the exquisite flower studies for which he is justly famous. He demonstrated on the lecture table, by means of Marion's "Quick Print" gaslight paper, the ease with which it was possible to obtain hard or soft results from a given negative as required. To produce soft results with this paper he used a very strong metol-hydroquinone developer, and when it was just possible to see all detail in the print he quickly transferred it to a water bath to which had been added a trace of old oxidised developer. When sufficient density had been obtained the print was fixed in an ordinary hypo bath to which had been added a 10 per cent. solution of chrome alum in the proportion of 1 oz. of the latter to a pint of hypo. All the members present were kindly presented by the lecturer with a copy of his study of "White Currants," which has obtained many awards, as a souvenir of the occasion.

**"THE St. Louis and Canadian Photographer."**—We are glad to see that the new editor, Mr. Tony O. Babb, has now swept his columns clean of hints on cookery, beauty culture, and notes of domestic interest. The March issue before us shows us that he is able to make a magazine with a thoroughly good programme of articles for professional photographers. But he ought to punish the draughtsman who designed the horrible design around a very pleasing half-tone on the cover.

**EDMONTON and District Photographic Society.**—A change of secretary has taken place by the appointment to this office of Mr. A. E. Warfolk, Main Avenue, Bush Hill Park, Enfield.

## Commercial & Legal Intelligence.

... Ltd., the registration of which was announced some ... has had its board strengthened by the accession of ... Holmes, who for a considerable period held the position of Librarian at Windsor Castle, from which he recently ... The progress of this undertaking will probably be watched ... little interest in circles where the names and achievements of ... Shepherd and Mr. James Cadett have been long and ... known. The programme is understood to include both ... and the highest class of art work.

**WESS Case.**—Judge Bacon, at Bloomsbury last week, had ... the claim of Messrs. Bale, Son, and Daniellson, printers, ... Titchfield Street, against Miss Gertrude Leutner, a vocalist, ... professional name is Miss Gertrude Lonsdale, of Kensington ... dens, for £10 5s., alleged to be due in respect of some ... phic posters prepared to her order. A jury had been sum- ... his Honour having been informed that the accuracy of ... ges was questioned, asked why eight gentlemen should be ... give an opinion on such a matter. Mr. Mould, barrister, ... plaintiffs, said that defendant ordered some posters to be ... from a photograph, and when showed the proof she said ... was a squint in one of the eyes. It was pointed out that ... be rectified, and another proof could be prepared. Defen- ... ever, said there was no time, as the posters—600 in ... had to be sent off the following day. The alteration was ... the order executed. One of the posters was then fastened ... all of the court by the side of the witness-box and in full ... the jury, who, after a brief deliberation, came to the ... that the posters did not constitute a good likeness of the ... and his honour gave judgment for her, with costs.

### NEW COMPANIES.

**re's.**—£3,000, in £1 shares. Chemists, druggists, manu- ... of photographic apparatus, etc. No initial public issue. ... **M AND Co., LTD.**—Capital £10,000, in £1 shares. Ob- ... acquire the business of mount and album manufacturers, ... rried on by Fordham and Co., at Lensden Place, Golden ... i, and at Euston Buildings, London, and to carry on ... and the business of manufacturers of and dealers in photo- ... materials, and lenses, optical, scientific, and other ... s, etc. No initial public issue. **rs. and Wainwright.**—£10,000 (£1). To take over the busi- ... nographic dry-plate and material makers and dealers carried ... L. Wratten at 75 and 78, Canterbury Road, Croydon, as ... and Wainwright. No initial public issue. First directors ... two nor more than five): F. C. L. Wratten, S. H. ... and C. E. K. Mees all permanent, subject to holding £500 ... n). Qualification of ordinary directors, £10.

### THE BOLT COURT SCHOOL.

of the L.C.C. School of Photo-Engraving and Lithography ... 19th has been published, the delay in issuing the handsome ... ng due to the endeavour of the School to print so many ... plemental illustrations on the premises. We will find ... report of the Principal, Mr. A. J. Newton, and defer a ... the plates, which are of the greatest possible technical ... process people, until a later issue.

th session, which commenced on September 26, 1904, closed ... June 30, 1905. The total number of individual students ... has been 488 as compared with 398 last session. This ... remarkable, as the limited accommodation afforded for ... classes is more than ever noticeable, and, as I stated ... the crowded state of the classes naturally reacts somewhat ... upon our numbers and attendances.

tion of the students can be classified as follows:—

... ..	288
... ..	147
... ..	5
... ..	48
... ..	488

age was 21.5 years.

The following summary shows how the activities of the students have been distributed:—

Individual students entering only for photo-engraving classes...	257
Individual students entering only for art classes ... ..	153
Individual students entering only for lithographic classes ...	32
Individual students entering for both photo-engraving and art classes ... ..	31
Individual students entering for both lithographic and art classes ... ..	13
Individual students entering for both lithographic and photo-engraving classes ... ..	2

488

The return of attendances has already been submitted, and on the whole is slightly better than last year, which is gratifying, when it is remembered that the character of our trade makes overtime a frequent necessity.

In the photo-engraving classes the work has been very good, and many blocks have been made by the students for the prospectuses of the Council's educational institutions and the Horniman Museum. Instruction in the making of tri-colour photo-engravings has been much in demand, and more finished work has been done than ever before, the installation of the power-platen press being of great advantage in enabling students to see the results of their work. Some of the examples lent us by the Board of Education, South Kensington, and reproduced by this method, it is hoped may be of use for art examples. In the day process classes we have had larger entries than ever before.

In the lithographic classes the work has been good. Mr. Baxter finds that instruction in colour work is most in demand, and sixty-five subjects have been reproduced in from two to eleven colours, on the whole satisfactorily, considering the difficulty of doing it in artificial light, besides thirty-five in one colour only. The total number of stones drawn has been 378. Mr. Howard's map and plan class has been considerably larger than ever before, and the work shows a great improvement.

In the design class Mr. Turbayne reports good results, and less poor work than in any previous session.

In the drawing classes Mr. Rea reports that the attendance and progress made by the students are quite satisfactory. We have had a large number of new young students, many of whom have done creditably and will do good work in future. The success of the pictorial and decorative composition class under Mr. Seymour has proved fully up to expectation. The Sketch Club has again been a feature of this year's work, and many distinguished artists have favoured us with their criticisms. Mr. Nelson Dawson has designed a silver badge, and Mr. George Frampton, R.A., who has always shown the greatest interest in the school, has presented, for the next ten years, a replica to become the property of the student doing the best work in the drawing classes and Sketch Club."

**THE International Exhibition of Photography.**—By a decree of the President of the French Republic, the buildings of the International Exhibition, which is to be held in the Grand Palais des Champs, Elysées, are made a customs house, and all exhibits will be sent direct there without examination at the frontiers. The office of the Commissariat of the exhibition is situated at 13, Avenue de la Motte-Picquet, Paris.

**ROYAL Institution.**—The following are lecture arrangements at the Royal Institution, after Easter:—Professor G. Baldwin Brown, two lectures on Greek Classical Dress in Life and in Art; Professor William Stirling, three lectures on Glands and their Products; Rev. J. P. Mahaffy, two lectures on (i) The Expansion of Old Green Literature by Recent Discoveries, (ii) The Influence of Ptolemaic Egypt on Græco-Roman Civilisation; Professor William J. Sollas, three lectures on Man and the Glacial Period; Professor Charles Waldstein, three lectures on English Furniture in the Eighteenth Century; Professor Sir James Dewar, two lectures on The Old and the New Chemistry. The Friday evening meetings will be resumed on April 27, when Professor John W. Gregory will discourse on Ore Deposits and their Distribution in Depth. Succeeding discourses will probably be given by the Hon. Charles A. Parsons, Professor J. H. Poynting, Professor Arthur Schuster, Mr. Leonard Hill, Professor H. Moissan, and Professor Sir James Dewar, and other gentlemen.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper.

No notice is taken of communications unless the names and addresses of the writers are given.

### ELECTRICAL ILLUMINATION IN THE STUDIO.

To the Editors.

Gentlemen,—In the article, entitled "A New Artificial Light Studio," which you published in the current issue, attention is drawn to the use of flaming sunlight arcs, which are now so popular for street illumination, for photographic use. A similar idea has been in my mind for some time, and I have been longing for an opportunity of trying the effect of using four such lamps for studio lighting, because I think that by using orthochromatic plates in the yellowish light given by these lamps, a high sensitiveness, and approximately correct colour rendering, would be obtained.

The important matter of cost is one of interest, and I was delighted to find that four "Excello" arc lamps, each taking six amperes and forty-four volts, may be run in series at a total cost of 1d. per lamp per hour. This is the actual cost at Newcastle-on-Tyne, and as each lamp is said to be of 1,600 candle-power, the total cost for a light of 6,400 candle-power is 4d. per hour. The illuminating power of ordinary arc lamps consuming the same quantity of current is said to be 475 candle-power.

More powerful illumination may be obtained by using four 12 ampère "Excello" arc lamps, working at forty-seven volts, in series, which give 4,500 candle-power per lamp against 1,365 candle-power obtained by using the ordinary arc lamps consuming the same current.

I appreciate the value of the violet rays obtained from the ordinary, or enclosed, arc lamps, for photographic purposes, but they do not help the photographer to obtain correct colour rendering, and it is a question that can only be settled by experiment whether the use of open or enclosed arcs with ordinary carbons and ordinary plates is more economical, and gives better results, than using flaming sunlight arcs and orthochromatic plates. To be of value the result of such an experiment should be published with full data.—Yours truly,

ARTHUR PAYNE.

Newcastle-on-Tyne, April 2, 1906.

### THREE-COLOUR PORTRAITURE.

To the Editors.

Gentlemen,—In the report of my lecture entitled the "Possibility of Portraiture in Colour," published in the B.J., the following paragraph occurs:—"The most serious drawback to the use of this or any other 'colour' process for portraiture is the long exposure necessary, three minutes being about the minimum, and five minutes the average time required, even under the best conditions of lighting, and with a lens aperture of  $f/3$ ."

I quoted three minutes as being my minimum, but all my colour-negatives were taken during the winter months, between two and three o'clock in the afternoon.

Within the last month Messrs. Sanger Shepherd have introduced new light filters and plates that decrease the exposure by about one-half.

Taking into consideration the increased power of the light at this time of the year, and the quicker plates and filters, it should be possible to reduce the time necessary for the three exposures to quite within one minute.—I am, yours, etc.,

S. ELWIN NEAME.

Coverdale Road, Shepherd's Bush, London.

April 3, 1906.

### MEASURING SHUTTER SPEEDS.

To the Editors.

Gentlemen,—In your remarks following my letter of March 26, you say your formula would not be correct for so wide an angle as 40 degs., as it only holds good for small angles.

This is, of course, hypothetically the case—that is to say, the acceleration of a pendulum with a small angular movement more nearly approaches the true harmonic motion than when the angular movement is great. But for all that, the error with an angle of 40 degs. would be so slight that the formula, if of any value at all, should work out the figures somewhat approximating correctness, and yet, as I pointed out last week, it does not appear to come within 50 per cent. of the results by the other three methods. However, if you would like to put your formula to a test more suited to its requirements, I will, with pleasure, expose a plate with a shutter test under the desired conditions.

You say you fail to see how the constant  $\frac{2}{\pi}$  in my formula makes

the necessary correction for the harmonic motion of the pendulum. It is based on the law that in such a motion the velocity in the middle of the swing is equal to eleven times the length of the swing, divided by the periodic time.

I see Mr. Douglas Carnegie—who, I am sorry to see, enters the discussion in rather an unfriendly spirit—writes from Blackheath. If he would call on me I should have pleasure in showing him my apparatus, and could give the reasoning by which the fraction  $\frac{18}{79}$  the

(not  $\frac{17}{79}$ th, as printed) is arrived at.—Yours obediently,

Bala Lodge, Blackheath, S.E.

ARTHUR A. WATKINS.

April 3, 1906.

### HOW TO SOLVE THE PROOF PROBLEM.

To the Editors.

Gentlemen,—As bearing out what has been said regarding the toning of proofs, I had sent to me recently some proofs forwarded to my customer from Mr. D. D'Arcy's studio, Dublin, with the request that I should tone them. On the back of each proof was stamped, "Proofs to be returned, with the number required marked on the back." I noticed that there were two whole-plate and three cabinet proofs (five positions). All had been carefully retouched. I considered that Mr. D'Arcy was entitled to some reward for his work, and replied to my lady customer:—"Dear Madam, I am sorry I cannot tone these proofs as it is against the rule. Besides, they are stamped with what looks like indelible ink, which is sometimes done for the photographer's protection, the proofs being returnable."—Yours faithfully,

HERBERT SPACKMAN.

Park Close Studio, Corsham, Wilts.

### COPYRIGHT IN NORWAY.

To the Editors.

Gentlemen,—Having concluded to lay before the Storting a new law for copyright of photographs, we want to collect everything of value that will make it fully clear to the members how the law now acts, and its faults and advantages.

There is one point we seem not to have clear, viz., Does the Berne Convention protect a photographer (fully protected here) in England, and vice versa? If so, can you tell me where a copy of such law is to be had?

According to our laws of March 12, 1877 (Sect. 2), each photograph must be marked with "Einberettiget," the year and photographer's name.

Sect. 8 says that by mutual consent between two countries the copyright can be extended to foreign photographers, but if Sect. 2 is suspended it requires the King's sanction. I have your Almanac of 1906 before me, and have read with interest all about copyright.—Respectfully yours,

A. B. WILSE.

Christiania.

[We may say to our correspondent that the text of the Berne Convention is issued in this country by the Government printers, Messrs. Eyre and Spottiswoode, of New Street, Fleet Street, London, E.C., although presumably, as Norway subscribed to the Convention in 1889, the Norwegian Government printers would issue it in Norwegian in that year. As we understand the Convention, it is necessary for a photographer in the country of origin, that is to say an Englishman in Great Britain, to comply with the formalities of his country, and he then obtains in the foreign countries subscribing

Convention a protection granted to natives of those countries. registration is enforced in Great Britain, but not the marking of copies. It follows from this that an English photograph of its way into Norway cannot be copied with impunity even if not the marking "Einberettiget."

As far as we can gather the law in Norway of 1877 only applies relations as regards copyright between Norway and countries do not subscribe to the Convention. At the present time there is a similar arrangement between Great Britain and the United States, is a non-convention country.—Eds., B.J.P.]

## THE KEEPING QUALITIES OF GELATINE NEGATIVES.

To the Editors.

Gentlemen,—Much as have been written respecting the keeping qualities of gelatine negatives versus collodion, and also their discolouration or not varnished by printing. I am enclosing you a few for your information and comment. I am not sure that these markings have referred to before. It would be instructive to know their causes. The plate stains, clearly not the result of hypo. or silver printing plates, showing stains only where retouching medium covers the usually considered some protection against the stain from printing: looked at from the back, it has some of the appearance of half-plate stains. The fourth plate is notably free of stain from the printing paper came, but round where it has been exposed to the atmosphere, charged probably with gas and sulphur, it has become darkened. These are but samples of several I have met in going over a lot. The fourth negative is an exceptional one and hence its outer edges got exposed more than usual, but it nevertheless indicates that gelatine negatives need protection beyond printing paper, and that they deteriorate from other causes than hypo may or may not be in the power of the user of the plate to prevent.

The stains visible on the quarter-plates in this case, you will see are on plate not varnished, but are not confined to such, hence evidently the medium has something to do with this. Perhaps you will be able to throw some light on it, as it is a serious matter to have a lot of good negatives and find them ruined. Thanking you for your participation, I am, yours,  
CERAMIC.

March 26, 1906.

With regard to the stain on the half-plate negative, this is certainly to some extent due to the plate not being thoroughly freed from hypo, as the characteristic taste can be at once detected. Two of the quarter-plates, which have been retouched, show distinctly that the medium has been applied, a slight increase in density, and is very easily explainable on the ground that the resinous substance in the medium has become oxidised and darkened. Both these also show on the back brilliant colours due to thin films, and in the case the complementary colours are distinctly seen by transmitted light. This looks as though the retouching medium had penetrated the gelatine and formed a thin film between the same and the glass. The third quarter-plate negative certainly shows the action of the air, and possibly also some action from fingers not very clean. This serves as a warning to all, to varnish their negatives, and considering that now, excellent cold varnishes can be obtained commercially, which can be applied in a minute or two with a brush, there is no reason why varnishing should not be as easily performed as fixing.—Eds., B.J.P.]

## ARTISTIC LENSES.

To the Editors.

Gentlemen,—I have been extremely interested in the information at the anachromatic lenses of MM. Puyo and de Pulligny you have supplied to us lately. There is one important point, however, in the use of these lenses, about which I have failed to find any mention, and that is the question of exposure. It would be interesting to know the relative increase in the exposure necessary to record green, yellow, and red fringes of the image, for in the latter case the exposure must be very prolonged. It may, of course, be shortened by using colour-sensitive plates. Perhaps someone who has been experimenting with this type of lens may be willing to publish this information.—Yours truly,  
ARTHUR PAYNE.

Newcastle-on-Tyne.

## Answers to Correspondents.

\*. All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\*. Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*. Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

\*. For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

S. Porter, 11, Marshfield Road, Chippenham. Photograph of the Employees of Sazby & Farmer, Ltd., Chippenham.

F. A. Crook, Sandlea Villa, Datchet, Bucks. Photograph of the Plough Inn, Datchet.

F. Melton, 116, Castle Road, Scarborough. Photograph of a Storm at Scarborough.

W. F. Foster, 110, King Street, Southsea, Hampshire. Photograph of Threes White Mice as carried on British Submarines.

Black & Cross, 15, Park Road, Scarborough. Photograph of a Wave on the North Bay, Scarborough, entitled "The Giant Wave."

P. Entwistle, 4, Windham Street, Blackburn. Photograph of a Dog on a Table entitled "Little Jim III."

VARIOUS.—Please tell me the maker of the "Diamond" brand collodio-chloride papers, also "Minerva," and the respective agents in this country. Second, are there any disadvantages in using a 1.1 lens for smaller work, presuming the studio is long enough?—DIAMOND.

1. Trapp and Munch. Agents, L. Trapp and Co., 89, Chiswell Street, London, E.C. 2. None, except that the sides of the bellows are more illuminated by the large lens, and a diaphragm in the camera may be advisable.

STRIPPING ALBUMEN PICTURES.—I shall be glad of information as to the following:—Is it possible to use a plain albumenised paper (of course not sensitised with silver), render it sensitive with bichromate, and use it as a transfer paper in a similar way to carbon tissue? What I want to know is, will the albumen emulsion leave the paper the same as gelatine will? I particularly require an albumen emulsion for transfer to metal, but up to the present I have found coating the metal a failure, as in developing the whole film washes off. A gum arabic film would do if it is possible to transfer that in any way as in carbon. Gelatine or fish glue is of no use whatever.—A. S. This subject is dealt with in "Ex Cathedra."

PATENT PLATE.—In reading the answer to correspondents about the three-colour in your issue for March 23, page 159, you advise the use of thin white patent plates to your readers. I cannot procure the plates, as I have written to several firms. They all say they do not keep or manufacture them. Can you recommend me to some firms who would supply for certain?—R. T.

We are surprised that you have any difficulty, as patent plate is a regular article of commerce, and is stocked by such houses as Fallowfield, Houghton, Penrose and Griffin, etc. It is usually made in four thicknesses—No. 1 about 1-16, No. 2 about 1-12, No. 3 about 1-10, and No. 4 about  $\frac{1}{8}$  inch thick. Any of the above firms would supply you.

J. HITCHINS.—We have no hesitation in saying that what you call pinholes are due to air bells clinging to the gelatine during

development. Pass a tuft of clean cotton wool on the tips of the fingers over the plates immediately after pouring on the developer.

**STARCH MOUNTANT.**—In a recipe for the above, it is stated, to be mixed with salicylic acid—i.e., two drams to 5 oz. water—is the acid added as a preservative, and would it have any effect upon C.C. prints?—OLD CROW.

Salicylic acid is used as a preservative only, and is not likely to have any effect upon the silver image when used in small quantities. We may point out that as the solubility of this acid is only 1 in 500 of cold water—that is practically a grain per ounce—there would be about 115 grains of undissolved acid in 5 oz., and we are not prepared to say that this would not attack the image.

**SOLVENTS FOR CELLULOSE.**—Will you inform me what solvents there are for celluloid other than amyl acetate and acetone? Is there anything of an oily nature?—A. R.

Celluloid is soluble in wood naphtha, propyl and butyl alcohols, and also glacial acetic acid. We do not know any oily solvent. It might be possible to dissolve in glacial acetic acid, and then add castor oil, but being ignorant of what the solution is for we cannot say whether this would be suitable.

**THIOCARBAMIDE.**—In "Work" of November 25, 1905, page 322, in an article on "Chemical Compounds Used in Photography," there is a statement that amm. sulpho-cyanide when heated undergoes a change to thiocarbamide, and also that the latter used in a developer causes reversal of image (positive from positive and vice versa). 1. Are these statements correct? 2. If so, is it anythink like easy to produce the change on a small scale, say an ounce or two, because thiocarbamide is unobtainable or, at least, not listed in catalogues, in N.Z.? 3. What is the correct proportion for use in developer as above?—GEO. T. R.

1. Yes. 2. The following is the method of preparing thiocarbamide from ammonium sulpho-cyanide:—About 500 grains of well-dried amm. sulpho-cyanide are placed in a flask, a thermometer inserted, and the whole then placed in an oil bath and heated to 170 degs. C. for two hours. It is allowed to cool down, and when it is 100 degs. C. is treated with its own weight of warm water (80 degs. C.). When the whole has dissolved the solution is filtered at once through a small plug of cotton, for the purpose of separating a black substance always formed in small quantity, and then left to crystallise. After some hours the liquid yields an abundant crop of long silky crystals, which are drained off and pressed between blotters and again crystallised from as small a quantity as possible of boiling water. Several crystallisations are needed to get the thiocarbamide perfectly pure, and it must not be dried by heat, but in vacuo over sulphuric acid. 3. The developer recommended by Major-General Waterhouse, who worked out the process, is:—Eikonogen, 1 part; sodium sulphite, 1 part; lithium carbonate, 1 part; water, 10 parts, to which is added a few drops of a solution of thiocarbamide and ammonium bromide, or of a compound of 4 parts thiocarbamide and 1 part ammonium bromide.

**FLASHLIGHT.**—Through your correspondence column I should like to learn, is there any really smokeless, instantaneous flash-powder to be obtained anywhere. I have used powder from several makers, all giving off dense smoke, and sometimes with a very loud report that was exceedingly objectionable. Can you advise where to obtain formulæ of various mixtures with which I could experiment, and possibly find a mixture that I could myself vary, so as to give a quicker or slower flash according to need. I would like a quick, comparatively silent, flash, with say 4 oz. powder, and little smoke.—F. E. G.

We know of no flashpowder which is perfectly smokeless, although recent powders, such as the Agfa, Krebs, and that supplied by Houghtons for their ideal lamp, are a good deal better than older products. You will find a large number of formulæ in the "Almanac" on pages 749-750.

**PERSULPHATE.**—I should feel obliged to you to let me know how to use the persulphate of ammonia and carbonate of soda as hypo-eliminator (B.J.A. formula). Should I put the plate in the persulphate directly after taking it out of the hypo and before

washing, or should I wash the plate first? How long is the plate to be left in the persulphate?—P. LAÛROIX.

The plate should be washed for about half-a-minute and immersed in the solution for about five minutes.

**RETOUCHING** (Reply to H. E. D.).—1. As a retoucher you are very inexperienced, but have made fair progress for the few months that you have devoted to the art. Your touch is too spotty and disconnected, and requires a bolder grain for a head of this size. Better blending and gradation of tones would improve the effect. You preserve the likeness, but your modelling is very faulty. Increase the high lights and clear up the shadows. Under the skilled guidance you should finally make a good retoucher. 2. We do not care to suggest the wages you could ask, as you are at present a very weak worker, and the mention of low rates in these columns may be injurious to more skilled employees.

**RETOUCHING** (Reply to L. M. E.).—1. Your work is lacking in brightness and style. Smoothing up faces is only part of the retoucher's duties. Modelling must be strictly attended to, the high-lights generally slightly increased; the half-tones fully respected, and the shadows not unduly removed. Excessive lights such as on the lips of the young woman should be knife-cut. Preservation of the likeness is your best quality. Space will not permit instruction in retouching in these columns—we can only criticise. Consult our advertisements for improving lessons. 2. Refer to reply to H. E. D.

**STRAITFORD.**—We are not aware of any such photographic appointments being filled by open examination. You had better apply to the Photographic School, Polytechnic, Regent Street, London, W.

**PHOTOGRAPHIC RECORD.**—A quaint antiquarian ceremony was observed last week, when Sir Benjamin Stone, M.P., and several other members of the National Photographic Record Society were admitted to the "freedom" of Highgate according to the ancient rites. The ceremony took place at the Old Gate House Hotel, when Mr. Potter, a local antiquary, who acted as "father" to the new freemen, administered the oath, which was sworn on a pair of stag's horns, which were mounted on a pole. The oath ran:—"Take notice what I now say to you, for that is the first word of your oath—mind that! You must acknowledge me to be your adopted father, I must acknowledge you to be my adopted son. If you do not call me father you forfeit a bottle of wine; if I do not call you son, I forfeit the same. And now, my good son, if you are travelling through this village of Highgate, and you have money in your pocket, go call for a bottle of wine at any house you may think proper to go into, and book it to your father's score. If you have any friends with you, you may treat them as well but, if you have money of your own, you must pay for it yourself. You must not eat brown bread while you can get white, except you like the brown the best. You must not drink small beer while you can get strong, except you like the small best. You must not kiss the maid while you can kiss the mistress, except you like the maid the best or have the chance to kiss them both." Each visitor then kissed the horns, signed a register, and received a certificate of freedom.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Exhibition of portraiture by Herr Dührkoop, Hamburg, opens at B.J. offices on Tuesday next, April 17.

The use of the anachromatic lenses a variety of effects is obtainable according to the make-up of the lenses supplied in special sets. (P. 285.)

Filters made from permanganate, chromium, etc., are the subject of further notes by T. Thorne Baker. (P. 284.)

Reaction of pyro compared with other developers as regards the gelatine film has been studied by MM. Lumière. P. 285.)

Producing postcards in quantity W. Foster Brigham calls attention to time-saving methods and devices in printing, development, and drying. (P. 287.)

Technical history of engraving, read before the Edinburgh Photographic Society by George M. Aillman, appears on P. 288.

A satisfactory report of the Eastman Kodak Company has led to a notable rise of Kodak shares on the Stock Exchange. (P. 291.)

Dyes for red-sensitiveness and a midget repeating back are the subject of the week. (P. 292.)

## EX CATHEDRA.

### An Exhibition of Portraiture.

We are pleased to be able to announce that an exhibition of portraiture by a very accomplished and versatile professional photographer, Herr R. Dührkoop, of Hamburg, will be opened at the offices of the BRITISH JOURNAL OF PHOTOGRAPHY on Tuesday next, and will be available for inspection by the public daily between 10.30 and 4.30 (Saturdays, 10.30 to 12.30). Herr Dührkoop has shown but little of his work in England, although the few pictures on the walls of the "Royal" and "Salon" have suggested the strength and variety of his photography in portraiture and figure studies. His twenty exhibits at Birmingham convinced us, when we visited the gallery of the British Artists, that we had in Dührkoop a wielder of the camera of an exceptional order. The present exhibition is the outcome of that impression and of a visit to Hamburg, where, by Herr Dührkoop's courtesy, we were able to collect the examples of his work which fill the small gallery set apart for exhibition purposes at our offices.

\* \* \*

### To Assistants and Others.

It has come to our knowledge—indirectly, not from the complainants themselves—that the hours during which the recent exhibition of colour photography was open, and during which, also, the present collection of Herr Dührkoop will be accessible, were such as to prevent a great many who are in business during the day from paying a visit. We confess to some surprise that requests for an evening opening were not addressed directly to us, for we hope we may assume the belief among all classes of our readers that our desire is to leave no stone unturned in contributing to the progress and elevation of photography and the advancement of photographers' varied interests. Therefore, we desire it to be known that we are prepared to open the present exhibition for one evening in every week, and we beg those belonging to the large class who are occupied during the entire day to advise us by postcard of the night most suitable. We shall then be assisted in fixing an evening for opening, and will make further announcement next week.

\* \* \*

### Filtering Developing Solutions.

The exclusion of air during the process of removing undissolved matter from developing liquids by filtration has received the attention of a German inventor, by whom a self-contained apparatus for the purpose has been patented. It consists of two bottles fitted airtight on either side of a stopper. The stopper has two holes passing through two tubes, the upper end of one tube being flush with the upper side and the lower end of the other tube flush with the lower side of the

stopper. One tube is packed with glass wool or similar filtering medium. A rough sketch will show the reader that on one bottle being filled (with the liquid to be filtered) connected to its companion, and the whole then inverted, the liquid flows through the filter from one bottle to the other.

### The Northern Exhibition.

The time draws near when the doors of the Manchester Athenæum are to admit the public to the Northern Exhibition. The opening ceremony and *conversazione* takes place on April 27, and during the nine days that the exhibition remains open there is a programme of accessory attractions in the way of lantern lectures which, we hope, will prove additional incentives to a large attendance. The lecturers include S. G. Kimber, Fred W. Saxby, Dr. Wm. Murray Cairns, Dr. John W. Ellis, Godfrey Bingley, and W. A. Clark. Our readers in the North should bear in mind this succession of opportunities, and couple with it the fact that a season ticket to the exhibition is obtainable for half a crown. The judges at this year's Northern are Archibald Cochrane, Ernest Marriage, F.R.P.S., and Frank M. Sutcliffe.

**A Classic of Photography.** It may interest students of the history of photography to learn that among the recent additions to the technical public library of the Patent Office in Southampton Buildings is a copy of the rare and important work by Victor Fouqué, "La Vérité sur l'Invention de la Photographie." This volume, as we have had occasion to point out when correcting the errors of hasty writers on the evolution of photography, contains a large number of the papers and letters of Nicéphore Niepce, whose work in detail did not become public until the issue of Fouqué's memoir. The admitted aim of the writer is to assign to Niepce the sole honour of the discovery which became known as Daguerreotype, and in its pursuit several natural conclusions are ignored or laboured. Nevertheless, the work is one which everyone desiring to study photography in its embryonic stages must consult, and we would wish that the Patent Office or some other library in London would acquire also the "Historique de la Découverte de la Photographie," written by Niepce's son Isidore, no copy of which, so far as we have been able to discover, is accessible in London.

### The Value of Miniatures.

At Christie's auction rooms, last week, there was a sale of the collection of miniatures, snuff-boxes, and other objects of vertu, formed by the late Lady Currie, and some very high prices were realised for the miniatures, of which there were about sixty. One of them, painted on a playing-card, was a portrait of Henry, Prince of Wales, eldest son of King James I., by Isaac Oliver. This picture was knocked down for no less a sum than £924. Another miniature—a portrait of a gentleman—by the same artist fetched £210. One by Hilliard made £357, and one by Conway, initialled "R. C.," 1787, £315. At the present time there seems to be a strong revival of miniature painting which photography practically killed many years ago. In the early days of photography a considerable business was done in Daguerreotypes, and paper portraits for brooches, and lockets, many of which were coloured by the old miniature painters, and very good they were—the majority of them. Then the fashion changed and portrait brooches were no longer seen. Now the fashion has changed again, and miniatures are once more in vogue, and very excellent are those on ivory, many of which are coloured on a carbon

base. Yet it is surprising that the genuine miniature can withstand the depreciation of its value in public estimation by the many and various cheap forms with which the market is deluged. We are aware there is a remunerative demand for these cheap miniatures, and for that reason we may offer our *apologia* for printing last week some notes on their production. Yet it is nevertheless a matter of surprise to observe the cheap aniline tinted portrait appended to—we can scarcely say adorning—the garments of many persons of apparent pretensions to be fashionable. The traveller in London can see that the coloured photo-miniature is not confined to Brixton and Upper Tooting.

### Posters at the R. P. S.

There is now on view at the premises of the Royal Photographic Society a collection of the posters submitted in the recent open competition organised by the society. The awards have been made by the editor of the "Studio" in collaboration with the Council, and the first place is taken by a very bold but simple design—the work of Thos. Cook. The subject is a conventional Eastern figure posed beside a camera (also conventional), and the only colouring in the composition is the big patches of orange which give the massed lighting effect on one side of the face. The poster, if not weighted with typographical additions, should be a bold advertisement for the autumn exhibition. And it is worth noting that in comparison with others submitted it is inexpensive to produce. We should say that for the limited edition which will be needed, the aerograph-stencil method of colouring would be economical and capable of giving the necessary vivid colouring which the design requires. On the other posters shown it is not possible for us to comment at length, but we may commend a Dutch figure subject by B. Fielder, and draw the attention of this and other exhibitors to the fact that a design for a poster and therefore for display by "sandwich men" should be upright in its position on the allotted space. A good many artists, we see, have made their composition "landscape way." The posters will remain on view at Russell Square until April 21, and no doubt some of the unsuccessful ones will find customers from makers of apparatus or materials. There are a good many which would make admirable and original showcards.

### The Bleach-out Colour Process.

According to a Zürich daily paper, Drs. J. H. Smith and Merckens have so far improved the bleaching-out process of colour photography that prints can now be obtained under a coloured original with half an hour's exposure to sunshine, and the editor states that the results which he saw were extraordinarily true and brilliant in colouring. It is also stated, on the authority of the above-named workers, that there is a reasonable hope that within a short time the sensitiveness of the paper may be so increased that direct prints in colours may be taken in the camera.

\* \* \*

### The Paris Photographic Salon.

The eleventh salon arranged by the Photo Club de Paris will be opened on June 9 in the Palais au Glace, Champs-Élysées, and will remain open daily from 10 to 6 until July 1. Although the fact is not paraded in the prospectus issued by the Photo Club, the Salon is international in its exhibition of photographs possessing pictorial quality, and prints, framed or unframed, will be accepted up to May 15 at the premises of the Photo Club, 44, Rue des Mathurins. The entry forms relating to the pictures

ould reach Paris by May 1. There is no charge for  
age, but the cost of carriage to and fro must, of course,  
borne by the exhibitor. In all probability work by the  
achromatic lenses of MM. Puyo and de Pulligny, to  
which we refer this week in continuation of the recent  
articles on the subject, will be largely in evidence, and  
those who can contrive a day or two in Paris during the  
month when the Bois and the boulevards are at their best  
could be doubly repaid for the journey.

### ARTISTIC LENSES.

another part of this issue we briefly review one of the  
newly introduced anachromatic lenses, of which a good deal  
has been heard at present, and which are to be represented  
by a number of photographs in the autumn exhibition of  
the Royal Photographic Society. The properties of the  
lenses being largely novel to many of those who have inter-  
ested themselves in them, it seems incumbent upon us to  
consider their behaviour in some detail, and so to answer  
the numerous questions in regard to them which have been  
addressed to us. It will be understood that we write of the  
lenses comprising single glasses and doublet lenses of various  
characters, the separate glasses fitting a single mount, the  
back portion of which is employed for making the chromatic  
correction.

There is no difficulty whatever in making this correction.  
The mount is, in the first instance, racked out until a line  
marked O coincides with back edge of opening in outer  
jacket. Sharp visual focus is then secured by the focussing  
adjustments of the camera, and when the picture plane  
has thus been adjusted to the focus for yellow rays, it is  
then adjusted to the focus for violet rays by racking in the  
mount until a scale mark representing the distance of the  
object is brought to the back edge of the opening in the  
outer jacket of the mounting.

The four objectives that the set is intended to make up  
are as follows:—A plano-convex lens in the front cell of the  
mount, with convex side towards the subject and the stops  
in front. This is intended especially for portrait studies of  
heads and shoulders, or half-length portraits against plain  
backgrounds with no accessories. With this arrangement  
the lens spherical aberration is reduced to a minimum in  
the centre of the plate, while at the margins aberrations  
of all kinds are very conspicuous. The full aperture is  $f/5$ ,  
 $f/8$  is the aperture advised. We found the definition in  
the centre to be fairly good, but no amount of stopping down  
effects much improvement in the marginal definition,  
hence the advice to use a plain background with no access-  
ories is certainly to be commended. For the particular  
work for which it is intended this lens is probably of great  
value.

The second arrangement is with the plano-convex in the  
back cell of the mount, with the plane side towards sub-  
ject and with the stops in front. The spherical aberration  
is then much increased, and small stops are necessary,  
being over  $f/10$  being admissible, while  $f/12$  or  $f/18$  are  
preferable. This arrangement of the lens is said to be of  
great value for figure studies, and more especially for landscape  
work, but it is not strongly advocated by the inventors, and  
our trials seem to indicate that it is in most cases much  
inferior to the next alternative, which is a single meniscus  
lens in the back cell, the whole arrangement being

similar to that of the ordinary single landscape lens. This  
is recommended to be used for small figures with acces-  
sories at an aperture of  $f/10$ . This aperture being some-  
what small for indoor work, it appears to us that the lens  
would probably be of greater service for landscape work.  
Most workers will, however, prefer the fourth arrangement,  
which seems from our tests to be capable of producing  
somewhat remarkable results.

This last modification is a symmetrical doublet with back  
and front meniscus lenses and a full aperture of  $f/5.5$ .  
Stopped down to  $f/8$  this covers a half-plate with a degree  
of definition that we did not expect. The field is very  
nearly flat, and at this aperture the definition on the  
focussing screen is very good right up to the corners of the  
plate. At  $f/5.5$  the central definition is markedly inferior,  
while coma puts in an appearance. The inventors recom-  
mend  $f/6$  to  $f/6.5$  for the production of what they call  
"synthesis," by which we understand them to mean detail  
softened by chromatic aberration. We tried the lens for  
copying a test diagram at  $f/11$ , and the definition on the  
screen left little to be desired, though very slight curvature  
was apparent. This symmetrical arrangement of the ob-  
jective, and the first one with plano convex lens in front  
cell, seem to us to be the most valuable combinations.

When focussed on a distance the extension of the camera  
from screen to flange is 10 inches with the symmetrical  
doublet. With plano lens in front cell the extension is  
only about  $7\frac{1}{2}$  inches, while with a lens in the back cell it  
is about  $12\frac{3}{4}$  inches. As before stated, all combinations  
give the same focal length, but considering the short exten-  
sion needed with the plano lens, and the advantages of long  
focus in the work for which it is specially intended, it  
appears to us that this lens might well be of greater focal  
length. This would reduce its aperture (which is now  $f/5$   
and would bear reduction to, say,  $f/6.5$ ), and necessitate a  
second scale for correction, for which there is plenty of  
room on the mount.

It should be noted that the lenses are all uncorrected,  
but selected and designed to give minimum aberrations.  
The doublet being of symmetrical construction shows no  
evident distortion, and very little coma at full aperture,  
and this last defect disappears at a smaller aperture, leav-  
ing barely appreciable astigmatism. This result is due in  
part to the wide separation of the lenses and their thinness,  
and to the narrow angle of view employed.

The plano lens in front of stop has no semblance of  
correction, its effectiveness depending entirely on the fact  
that such a lens with curved side towards object gives only  
a minimum amount of aberration in the centre of the field,  
and the centre of the field is practically the only part in-  
tended to be used.

The single lenses behind the stops are, of course, in a  
disadvantageous position, and small stops are necessary.  
We are inclined to think that these arrangements might be  
ignored, as the symmetrical doublet and the single plano  
will apparently do all that is necessary.

The single meniscus is not of the same form as the lenses  
used in the doublet. The former has a concave radius  
equal to its focal length, and in the latter the concave  
radius is about two-thirds of the focal length. Each lens  
is designed specially for a particular purpose.

Altogether we consider these new instruments to be a  
most interesting set of lenses, and of a kind which the  
portrait photographer will probably find to be of great  
value. A study of the book of MM. Puyo and de Pulligny  
shows that the design has been worked out on a very  
scientific basis, and, though uncorrected, these objectives  
are a long way in advance of the too common haphazard  
combinations of any cheap available lens fixed at any  
convenient distance from a stop.

# THE THEORY AND PRACTICE OF INTENSIFICATION.

## II.

WE now come to the precipitation of metallic compounds on the reduced silver image, the most successful case, perhaps, being that of chromium. A solution of a chromate rendered acid with hydrochloric acid will convert the image into a yellowish-looking picture, and the "bleached" image after washing may be redeveloped with an alkaline-reducing solution, when certain chromium compounds are precipitated upon the original silver and sub-haloid image, thus giving very considerable intensification to the negative, sometimes accompanied by slightly brownish coloration.

A H. and D. strip was read off before and after intensification, and the following were the results:—

	Fog Portion.	1st.	2nd.	3rd	4th.	5th.
Original .....	1.2	3.5	6.8	10.3	12.5	—
Intensified .....	1.9	5.5	9.9	15.3	19.8	—

If we compare the first portion with the third, we find in the first case:—

$$IN = \frac{5.5}{3.5} \text{ or } 1.57,$$

whilst in the second case:—

$$IN = \frac{15.3}{10.3} \text{ or } 1.49.$$

Evidently, then, intensification was slightly greater in the under-exposed portions than in the well exposed. This result was fully confirmed on intensifying a negative taken on a process plate, the details in the shadows coming up wonderfully clearly. It is interesting to note that both the original and the intensified strips gave approximately the same H. and D. speed number, and also that reversal commenced at the same time in each negative.

### The Chromium Intensifier.

In order to, if possible, accelerate the action of the chromate, I used a less stable compound than the potassium salt, employing instead calcium chromate. A solution of this (made acid with HCl) was prepared as follows:—

Calcium chromate .....	1.5 gms.
Water .....	100 ccs.
Hydrochloric acid .....	1.5 ccs.

About three minutes' immersion in this will suffice; the negative is then thoroughly washed and developed with a mixture of equal parts of the following developer:—

A. Hydroquinone .....	1 gm.
Pot. metabisulphite .....	1 gm.
Water .....	200 ccs.
B. Caustic soda .....	2 gms.
Water .....	200 ccs.

The redeveloper quickly decomposes the precipitated chromate, with the result that oxides of chromium adhere to the silver particles, and cause the intensification. A few minutes' washing is necessary after redeveloper.

On examining films before and after intensification with a high-power microscope, so that a magnification of 1,200 diameters was obtained, it was apparent that very small, if any, interaction takes place between the chromium oxides and the reduced silver particles. What seems to have taken place during intensification is the precipitation of the chromium

oxides in between the granules of silver, which therefore seem to incite precipitation.

### Uranium Intensification.

Uranium should be an extremely useful metal to us, but, unfortunately, it causes such a distinct coloration to the film, and, owing to the fact that it intensifies the shadows of low tones more proportionately than the high-lights or deep tones, the fog on the plate is much accentuated. The most powerful intensification is effected when using a bath containing an excess of uranium nitrate. The compound then precipitated on the image has, according to Otterberg, the formula  $(\text{UO}_2)_3, \text{K}_2(\text{FeCy}_6)_2, 6\text{H}_2\text{O}$ . Intensification is very rapid, and bright reddish coloration is imparted to the film, but it is possible that if the bath be prepared with an excess of ferricyanide and given a sufficient time to work, about as great intensification might be obtained as with the other.

The solution, when once mixed, does not keep well, and two solutions should therefore be prepared, as follows:—

A. Uranium nitrate .....	2 gms.
Acetic acid (B.P.) .....	5 ccs.
Water .....	100 ccs.
B Potassium ferricyanide .....	2 gms.
Water .....	100 ccs.

Three parts of A mixed with two of B give a powerful intensifier; two of A with four of B give a less powerful intensifier, which is more suitable for under-exposed negatives. The first-named solution was tested as regards its effect on gradation, and the result is shown in Fig. 1.

When intensifying with uranium it is essential to remove all traces of hypo from the film, and for this purpose a hypo eliminator is very useful. The deposit of ferrocyanide formed is removable by long washing, and also by aqueous solution of sulphites, so that it is not difficult to cope with cases of over-intensification. It is possible to avoid this loss of density by washing the plate in water containing a small percentage of acetic acid.

A noticeable feature with uranium intensification is that the gelatine itself becomes discoloured. Often very much so. The simplest way to remove the yellowness from the film is to soak the plate for a minute or two in a 5 per cent. solution of ammonium sulphocyanide previously to the final washing.

In the figure we see two characteristic effects of uranium intensification: the dotted curve shows the effect of intensification with negative of ordinary character; but should the plate be all over-exposed, we at once get intensification like 2, where the shadows receive more comparatively than the high-lights.

### The Permanganate Intensifier.

Text in importance comes the permanganate intensifier. It gives excellent results, and very great intensification can be obtained with it, the image being black. With a weak acid solution of potassium permanganate the image turns pinkish-brown, and after washing and redeveloping with hydroquinone or metol-hydroquinone the "bleached" image again becomes black, and regains density. Thus a strip before and after treatment with a weak bath gave the following results, from which it will be seen that at the conclusion of the operation "negative" was practically the same as before:—

	Fog Portion.	1st.	2nd.	3rd.	4th.	5th.
Before .....	1.5	1.9	3.2	6.2	11.5	18.5
After .....	1.5	1.9	3.3	6.3	11.7	18.7

When, however, we use a more concentrated solution of permanganate much greater intensification is obtained.\* Thus the following table shows the increments of density in a strip after treatment with a strong bath:—

	Fog Portion.	1st.	2nd.	3rd.	4th.	5th.
Before .....	1.5	1.9	3.2	6.2	11.5	18.5
After .....	1.5	2.1	3.7	7.3	13.0	21.2

Therefore recommend for intensifying with permanganate the following solution:—

Potass. permanganate .....	1 gm.
Water .....	100 ccs.
Con. hydrochloric acid .....	.25 cc.

The great density obtained by intensifying an actual negative with permanganate is apparently more difficult to obtain with the strip.

It need hardly be said that the negative should be entirely freed from hypo; when thoroughly washed it is placed in the above solution until it appears a bright red by transmitted light. It is then washed until the last wash-water does not appear crimson, *i.e.*, until all free permanganate is removed from the film. Finally it is redeveloped with an alkaline developer, such as hydroquinone and caustic soda or metol-hydroquinone. From curves of H. and D. strips plotted before and after treatment, and from actual negatives intensified, it is evident that the permanganate method wonderfully increases the shadow-details and under-exposed portions.

### Bismuth, Molybdenum, and Other Intensifiers.

Hydrogen peroxide in ethereal solution has at present failed to give any directly measureable results in my hands. A 1 per cent. solution of bismuth trinitrate acidified with nitric acid combines to a small extent with the image of a negative, and subsequent treatment with weak ammonium sulphide solution causes intensification; the method promises well, but at present it is difficult to avoid the slight production of universal fog.

A solution of ammonium molybdate and potassium ferricyanide, acidified with acetic acid, also produces alteration of the image, but the slight increase in density obtained is not in favour of its use.

On the whole, after experimenting with mercury, lead, copper, uranium, chromium, and manganese, one is disposed to give mercury the first place as an all-round intensifying agent, but I would again draw attention to the promising nature of the permanganate method, which, for reasons at present not clear, works better with an actual negative than with an actinometer strip.

In the third and concluding article I propose giving a reference list of modern intensifiers.

T. THORNE BAKER, F.C.S.

## THE TANNING OF GELATINE DURING DEVELOPMENT, ESPECIALLY WITH PYRO.

[There are several processes which require the use of a developer which does not tan the gelatine, and it has always been assumed that pyro was the only developing agent that exerted this action. In our issue for March 30, p. 245, a brief abstract was given of MM. Lumière and Seyewetz's article, which is sufficiently interesting to bear a full translation.—  
—B.J.P.]

Two developers, according to present ideas, alone possess the property of rendering gelatine insoluble during development. This insolubilisation, as is well known, is scarcely noticeable in the transparent parts of the negative, but is complete in those parts which contain a sufficient quantity of reduced silver.

In the present researches the authors have investigated two questions, the first as to whether the tanning is due to the actions which take place during development, and, secondly, whether it occurs when there is no silver. It has also been determined what part the pyro plays, and whether other developing agents exert the same action. In order to determine whether the actual operation of development was necessary to produce the tanning of the gelatine, sheets of gelatine were immersed in the following solution:—

Anhydrous sodium sulphite .....	30 parts.
Pyro .....	10 parts.
Sodium carbonate .....	30 parts.
Water .....	1000 parts.

It was found that the gelatine did not become markedly more insoluble whilst immersed for the ordinary time of development—ten minutes. It did not become more insoluble even if immersed in the above for an hour. When, instead of using sheet gelatine, negatives developed by other developers which do not tan were immersed in the above solution, no tanning action, even in the densest parts of the negative, could be detected. The presence of the silver alone cannot therefore be said to be a cause of the tanning action.

When, however, the sheet gelatine or negatives of the previous experiment were immersed in the pyro solution for several days with the access of air, it was found that the pure gelatine as well as that which contained silver became insoluble.

This experiment proved that the tanning action can take place without development, but that the latter action considerably accelerates the tanning. In order to explain these phenomena the action was tested in the absence of silver, and the following solutions were made up:—

1.—1 per cent. solution of pyrogallol.

2.—1 per cent. solution of pyrogallol plus 3 per cent. anhydrous sodium carbonate.

3.—1 per cent. solution of pyrogallol plus 3 per cent. anhydrous sodium carbonate and sulphite.

Sheets of gelatine were digested in wide-mouthed bottles half filled with the above solutions.

Solution No. 2 made the gelatine, after two days contact, absolutely insoluble.

Solution No. 3 gave the same result only after four days. Solution No. 1 produced no marked insolubilisation, even after a month.

It was seen that No. 2 solution, which produced the tanning most quickly, was that which turned brown most quickly by absorption of oxygen. No. 3 turned brown more slowly than the other, but it was deeply coloured when complete insolubility was reached. Solution No. 1 became only faintly coloured in the course of time.

These results led to the assumption that the atmospheric oxygen played some part in the tanning. In order to test this the experiments were repeated in closed bottles, with exclusion of the air. Under these conditions the above-mentioned solutions exerted no tanning action even in a month, a fact which appears to substantiate this hypothesis.

As the results obtained showed the necessity of oxidation of the developer for a tanning action to take place, it was thought that the same result could be obtained with other developers if the oxidation of the same was hastened. In order to prove this hypothesis, the experiments were repeated with the principal developers; that is, comparative trials were made with and without access of air.

Every day a piece of gelatine was taken out of the bottles and tried in boiling water. The result is shown in the following table:—

Developer.	1% Aqueous Solution.		1% Aqueous Solution + 3% Anhydrous Sodium Carbonate.		1% Aqueous Solution + 3% Anhydrous Sodium Carbonate + 3% Anhydrous Sulphite.	
	With access of air.	With exclusion of air.	With access of air.	With exclusion of air.	With access of air.	With exclusion of air.
Pyrogallol .....	The gelatine melts easily after 1 month	The gelatine melts easily after 1 month	Insol. after 1½ days	The gelatine melts easily after 1 month	Gel. insol. after 3½ days	The gelatine melts easily after 1 month
Hydroquinone .....	"	"	after 1 day	"	Melts easily after 1 month	"
Pyrocatechine .....	"	"	after 2 days	"	" "	"
Paramidophenol (base)...	"	"	Partly insol. after 1 month	"	" "	"
Amidol .....	"	"	after 1 day	"	Insol. after 3 days	"
Diamidoresorcin .....	"	"	after 1 day	"	Insol. after 1½ days	"
" hydrochlor...	"	"	after 2 days	"	" "	"
Metokinaosa .....	"	"	after 2 days	"	Melts easily after 1 month	"
Adurol .....	"	"	after 2 days	"	" "	"
Paraphenylenediamine ..	"	"	Gelatine melts after 1 month	"	" "	"
Eikonogen .....	"	"	insol. after 6 days	"	" "	"
Metol .....	"	"	insol. after 3 days	"	" "	"
Glycin .....	"	"	melts after 1 month	"	" "	"

In order to test whether it was the oxidation product and not the development that produced the tanning, the action of a well-known oxidation product, namely, quinone, was tested. This substance, which is formed by the oxidation of hydroquinone, is, as is well known, formed in development.

It was found that a cold saturated solution of quinone, 0.5 per cent., made gelatine, even with exclusion of air, quite insoluble, whilst hydroquinone is without action on the

gelatine. If this solution of quinone is added to a suitable quantity of gelatine solution it mixes well, but when the gelatine sets it becomes quite insoluble in boiling water. Twenty parts of a 0.5 per cent. solution of quinone make 100 parts of a 10 per cent. solution of gelatine insoluble. The tanning action is very similar to that by chrome alum formaline.

Finally, with a 0.5 per cent. solution of quinone a gelatine negative can be hardened as well as with formaline.

The above experiments prove conclusively that when there is no tanning action with other developers as with pyro, the reason is that other developers only very slowly absorb atmospheric oxygen in the presence of sulphite. As soon as they come under conditions which favour their oxidation tanning occurs.

It is worth while noting that under no conditions is complete tanning obtained with paramidophenol, and that the hydrochlorate of diamidophenol with an alkaline carbonate tans the gelatine more quickly with than without sulphite. The peculiar behaviour of paramidophenol may perhaps be explained by the fact that the oxidation product is insoluble in water, and only slightly soluble in solution of sodium sulphite. With amidol it is also seen that without sulphite the oxidation product forms a precipitate, but that in the presence of an alkaline carbonate and sulphite it does not do so. If there is sulphite used it oxidises more slowly, but still absorbs enough oxygen to produce tanning.

It is easy to grasp, from the above experiments, the mechanism of the tanning of gelatine when developing with pyro, and the reason why the tanning is more complete where the silver is reduced by the developer.

It may be assumed that the pyro is oxidised by the action of the bromine from the silver bromide, and that this oxidation

product, which is formed in the presence of sulphite, makes the gelatine insoluble, exactly in the same way as the quinone used in the free state did.

As regards the other developers, in that they do not produce the insolubility of the gelatine when used under normal conditions, it is probable that their oxidation products formed during development are decomposed by the sulphite.

A. AND L. LUMIERE.

THE official guide to Great Yarmouth, fully illustrated and descriptive of the pictorial and recreative features of the popular East-Coast resort, reaches us from the publishers on behalf of the corporation,

Messrs. Jarrold and Sons, Ltd., King Street, Great Yarmouth, by whom we believe it will be sent gratuitously to any applicant.

## THE RAPID PRINTING OF POSTCARDS.

The following article, from the current issue of "Photographic Scraps," deals with certain minor difficulties in postcard production such a way that we may well reprint it, with a reminder to our readers of the monetary importance of the postcard in many a photographic business.—Ebs. B.J.P.]

Dealing with a hurried order for postcards recently, our first difficulty was with our negative, which was steep in gradation and of a wall-like density. Evidently this would only produce soot and wash effects on bromide, and even with special treatment a unsatisfactory portrait would result.

### Negatives for Bromide Printing.

A new negative had therefore to be made. As a thin but "cony" negative, full of detail, was necessary to reduce exposure, a transparency was made on an Ilford ordinary plate, developed with diluted pyro-soda. This plate was fixed and quickly washed under tap for five minutes; absolute freedom from hypo not being essential in the transparency. It was then dried on both sides with a flannel cloth, and placed for three minutes in methylated spirit, for a few seconds' exposure to the air sufficed to evaporate.

The transparency was carefully retouched so that the resulting negative might be quite clean and free from spots. The name of the photographer and title of subject were written with liquid Indian ink in the ordinary way (not reversed) on the film side of the transparency with a pen. Of course the result on the card was reversed. Two negatives were produced from the transparency by contact, these being washed and dried in the same way.

The negatives were thin and "contrasty," but full of detail, quite fit for bromide printing, but as we only stock a few postcards the necessary quantity had to be procured from the local dealer. Luckily at the Ilford bromide cards we wanted, and on our expressing surprise at his being able to supply us off-hand with six gross of one make, he assured us that he stocked more Ilford cards than others combined, and was sure of a quick sale.

We had been using the standard Ilford metol-hydroquinone bromide formula for our enlargements, but in postcard-printing the margin of error is so small that we decided on the following developer, cheaper, and use hydroquinone is so much less expensive than metol.

No. 1.	No. 2.		
Hydroquinone ... ..	200 grs.	Potassium carbonate...	4 ozs.
Metol ... ..	120 "	Water up to ... ..	80 "
Sulphite of Soda ... ..	4 ozs.		
Water up to ... ..	80 "		

Used in equal parts.

### Printing Borders.

We proceeded to make a mask for printing the cards with a white border, which not only made them look and sell better, but also rendered any trimming at the edges unnecessary. When once they are properly arranged, bordered cards are as easily printed as plain. The mask was made by laying a post card on a piece of black wrapping paper on old 5 x 4 film, and then running round the card with a pencil a distance from this line equal to the width that the white border was intended to be, pencil-lines were ruled inside of and parallel to the lines first made. The centre-piece was then cut out with a sharp knife, care being taken to get the corners clean.

We next cut some thin strips from an old postcard about a quarter of an inch in width. Two strips were taken, one, a short one, being stuck on to the mask with its edge coinciding with the pencil-line round the original card, but on the side opposite to that from which the centre had been removed. A piece of card, rather longer than the other, was then stuck to the mask at right angles to the first piece, and again coinciding with the pencil line first made, and on the side of the line opposite to that from which the centre had been cut out. These two pieces of card were now so placed that when the sensitive card was pushed close up to them the white border round the card would be quite equal.

The mask being now stuck to the negative to be printed from and in the right position, all that was necessary to get that part of the card which was to appear on the card with a correctly proportioned white line, was to place each card to be printed with the top edge touching, but not overlapping, the two guides. These guides

were thick enough to enable one to easily and rapidly place the sensitive card in position but not thick enough to interfere with the pressure on the card of the printing-frame back, which might have caused loss of sharpness.

### A Time-Saving Printing Frame.

To print in the ordinary way would evidently have taken far too long, so that we devised a quick-printing frame quite simple and effective, but not, we believe, before used. The springs were removed from an ordinary half-plate frame, the hinged back placed in position, and two hinges screwed to the bottom half of the back and parallel to the pair of hinges already in position. The two hinged halves would have fallen back out of the frame, but were, of course, fixed to it. The frame was screwed up in the dark room one foot from a No. 5 Bray's burner, and the negative and mask, in position, fixed into the frame with gummed paper.

A light-tight box with exposed and unexposed divisions was obtained and sensitive cards unloaded into it. Without such a box quick production is impossible, the cards must not be kept wrapped up, or in envelopes, if speed is to be attained. The ordinary yellow light was placed so as to shine on the back of the printing-frame and negative, showing up the white guides, the naked gas being turned low.

A card was taken out of the unexposed division, placed sensitive side to the negative, and corner up to the guides. The card was held in position at the top, the lower half of the back was raised and pressed against the lower part of the card, this being sufficient to secure it. The hand could then be removed from the top of the card, the upper half of the back be raised and placed in contact with the postcard. The two halves were kept in contact with the card and negative by pressing with the hand. The frame being screwed up did not move. The gas was manipulated with the free hand and the exposure given. In the case referred to it was five seconds.

### Wholesale Development.

This may seem a complicated and elaborate method, but a dozen cards can be printed in the time it has taken to describe it. When the full number of cards were printed, development was started, the following dishes being used. One large one full of clean water for the preliminary soak, one 15 x 12 dish for developing, one full of water for washing after developing, and two fixing dishes full of hypo, three ozs. in twenty.

About a hundred cards were placed in the clean water, each one being put in separately, and care being taken to avoid air-bells. Forty ounces of developer were placed in the dish and about twelve cards were slipped singly into the solution. Here again air-bells had at all costs to be avoided, as the present prices of photographic cards do not allow for spotting.

As the cards were developed far enough they were rinsed in clean water. A rather longer time in development would not have greatly mattered, as the exposure was so timed that the end of the light action and the limit of the developing power of the reducing agent were reached simultaneously. When developing batches of cards in this way the operator must not run any risk of contaminating his developer, or staining the prints by putting his hands into hypo. An assistant should remove the cards from the water used for washing after development, and place them and keep them moving in the hypo. When about a hundred are in the one dish, the time when the last card of the batch was put into the hypo is noted, and a quarter of an hour's fixing from that time given. Meanwhile the other hypo dish is used.

When the first batch has been fixed the prints are put into clean water and the hypo used again, while the second batch fixes, and so on. With two persons working in this way, one of whom may be unskilled, a big batch is soon developed, and we managed ours in ninety minutes, changing the developer only four times.

### Washing and Drying.

As running water is useless for thick material like postcards the batch had to be hand-washed. Half a dozen changes were given, the cards being transferred from one large trough to another. Working at top speed each transfer to clean water took ten minutes.

An even more monotonous and tedious operation was yet to come, that of transferring the cards to the drying-racks. These racks had been made by a joiner while printing, developing and washing were in progress. With large batches they are a necessity, as a saleable card must be quite flat. To ensure this the flat-ruler system is almost valueless, and does not tend to improve the surface.

The racks were made by screwing  $\frac{1}{2}$  in.  $\times$   $\frac{1}{2}$  in. laths on flat boards, having the laths parallel to one another and  $\frac{1}{2}$  inches apart, or one inch less than the length of a postcard.

The cards, after any excess of water had been removed by blotting, were placed between the parallel laths film side up. To get them in, the cards had to be arched, and were so allowed to dry, thus counteracting the pull of the gelatine. A little curving when they were removed from the rack and about fifteen minutes under a heavy weight left the cards sufficiently flat.

The whole time taken for the batch of about a thousand, irrespective of the time taken to procure cards, fix frames, and make developer, was six hours. The drying was done spontaneously during the night.

I may mention that of the entire number of Ilford cards not one was rejected owing to defects in manufacture. This contrasted favourably with some cards I have used, which were plentifully supplied with metallic markings and spots of some foreign substance in the emulsion.

W. FOSTER BRIGHAM.

## A SKETCH HISTORY OF ENGRAVING.

A Paper read at the Sixth General Meeting of the Edinburgh Photographic Society.

### 1. Wood or Relief Engraving.

THE art or practice of representing things by incised lines on metal, stone, or other hard surface is of very ancient origin indeed. The great antiquity of carved documents is shown in the Bible. The divine commands were issued on tables of stone, and among primitive nations this seems to have been considered the most appropriate and durable method of perpetuating records. In such cases the letters were evidently cut with a sharp instrument of iron or perhaps prepared copper. Job says, "Oh, that my words were written, that they were graven with an iron pen and lead in the rock for ever." Here we have a foreshadowing of the afterwards famous niello work, from which might be said to have sprung the practice of printing from an engraved metal plate.

It is my intention to deal with engraving as one of the fine arts principally employed in translating the works of painters for dissemination by the press. In speaking of engraving generally, we are accustomed to infer an impression printed on paper from an original in the printing-press, so that in making a beginning it may be quite enough to start with the date when this important movement took place.

Broadly put, there are two great divisions in the art, viz., relief engraving and intaglio engraving.

In relief engraving the lines which are to make an impression on the paper are raised up on the original, while the spaces between them which are to appear white are cut away.

In intaglio engraving, on the contrary, the lines to appear black on the paper are sunk below the surface on the original, and the parts to appear white are raised up.

Wood engraving represents the first, and in inking this relief picture for printing a roller well-impregnated with ink is used, which, of course, only touches the raised parts.

Copperplate engraving represents the second, and in preparing it the ink is dabbed into the sunken lines and then the smooth bare parts are wiped perfectly clean by the use of a cloth and also the palm of the hand. Although in importance wood engraving does not come before copperplate engraving, still historically it undoubtedly does so. As a pictorial art, wood engraving in Europe goes back to the first quarter of the fifteenth century.

Germany has the distinction of having produced the first authentic and dated print. This print represents St. Christopher carrying the Infant Christ across a river, and was discovered in one of the oldest convents in Germany, the Chartreus of Buxheim, near Memmingen, and bears the date 1423. It is now in the possession of Earl Spencer. This illustration is in one of the very earliest block-books known, that is a book whose whole text was carved or engraved on wood, and the impressions taken by rubbing on the back of the paper instead of the steady pressure of the printing-press.

From the time of the St. Christopher till 1440, when Gutenberg popularised the printing process by his invention of movable types, engravers and those who drew for them were very circumscribed. It

was long before the engravers in Germany acquired anything like the skill of the printers trained by Gutenberg.

In Holland, however, the early printers seem not to have made such progress as the engravers. In Gutenberg's publications spaces were left in the printing for the capital letters, and were afterwards filled in with brush or pen, possibly in colour. As time went on this difficulty was overcome, and wooden blocks with the larger letters and illuminations or illustrations were printed from, so doing away with the illuminators' craft. Wood engraving continued to make progress particularly in Germany, but it was not till 1466, when an anonymous artist, known as the master of 1466, produced work of a high standard, that the art might truly be called an art. Following him was Martin Schongauer, an able artist whose influence was productive of a number of enthusiastic disciples who followed the teaching of their master with great success.

In 1476, Caxton, in England, published "The Game and the Play of the Chess," illustrated by woodcuts. The art of printing Caxton learned while trading in Holland during the reign of Edward IV. This seems to have been the earliest wood engraving printed in England.

It was not till the production of works by Albert Durer, the great promoter of the art, about the beginning of the sixteenth century, that a complete revolution in the art took place.

This great artist was not as the earlier men were, tied down to the rules of their teachers. His merits were entirely his own. Although Durer was himself a skilful copperplate engraver, the bulk of his compositions are woodcuts.

As wood engraving, or to speak more correctly, wood cutting, had been extensively practised already in Germany, these productions of his were executed on wood by skilful workmen, who had mastered the practice then followed of cutting with a knife instead of using a graver. There is little wonder that a man of Durer's great mental power and artistic genius should advance the art in which he was so interested.

While he lived, Durer was one of the greatest artists in Europe, being acknowledged so by such a dissimilar master as Raphael himself, with whom he was on terms of friendly correspondence.

Of Durer it might be truly said that he was a German in his art to the last, for although he had travelled during his youth in Italy at a time when the great artists, with Raphael at their head, were producing works influenced by the antique, we can find no evidence of their influence on the work of Durer.

The next outstanding name in the art is that of Hans Holbein, also a German. This great artist is historically interesting to Englishmen by the fact of having resided in London during the reign of Henry VIII., and been the first court painter we have of any artistic ability. Like his countryman Durer, Holbein was an artist of great versatility, designing decorations, painting portraits, and drawing book illustrations. As an engraver, his fame as the origi-

of the series of cuts known as "The Dance of Death" is world-famous. These masterpieces were engraved by one Lützelburger of Nuremberg, and were first published in Lyons in 1538, and consist of 150 cuts.

This series of engravings may be said to have closed the period of engraving which had gone on in Germany from the beginning of the fifteenth century.

Until the time of Holbein wood engraving was more conventional and it is now, it so circumscribed and limited itself in practice that it expressed what it had in hand with greater power, and his life closes the era of a school of engraving which has never been surpassed in its own way.

For the actual process of wood engraving, a description of the material and the tools used may be given.

All these early engravings were cut with a knife instead of a graver. It was necessitated by the work being done on wood blocks cut long way of the fibre, so that the workman had to cut sometimes across the fibre, and at other times along with it. To represent four lines no less than thirty-two or more cuts would be required in order to leave them clear on the surface. This was a slow and tedious process, requiring for fine work a neatness of hand very difficult to attain. Possibly this technical condition was the main cause of the artists, who drew for reproduction, suiting their lining drawing to the limitations of the craftsman's art.

From the time of Holbein onwards, for long wood engraving was in a stagnant state, probably on account of no great artist interesting himself in the art. About the middle of the eighteenth century the French revolution in wood engraving took place, the honour falling in England in the person of Thomas Bewick, born in 1753 near Newbottle-on-Tyne. This man, a copperplate engraver by profession, directed his attention to wood engraving, and produced work which went far beyond what had previously been seen. His practice was to get his effects by the simplest possible means, discarding the elaborate system of shading by laboriously crossing black lines, so common with the earlier men. Bewick never did so, but on the contrary crossed white lines on a black ground. This white line was his own invention, and has had far-reaching consequences on the history of wood-engraving.

It is generally considered that it was at this time that the new era of preparing the wood block came about, which consisted in lining the log of boxwood through crossways and executing the shading on the upstanding fibre, so that there was no trouble from the stringy fibre as in the earlier method. Coupled with this improvement was the substitution of the graver for the knife, greatly extending the field of possibilities and facilitating the execution of the work.

One of the great virtues of Bewick's work is due to the fact that he not only made the original drawings himself, but also executed the engravings.

He was all along a keen naturalist, and in 1798 published a "History of British Quadrupeds," and "British Birds," 1804. In both works a greater number of the illustrations are drawn and engraved by himself. These works are also remarkable for a series of vignettes and tailpieces, displaying an infinite amount of humour and pathos. Bewick had no teaching in his art, and his work was the outcome of his intense love of nature and the spark of genius which certainly shone in his. This white line of Bewick's made it possible for the wood engraver to become in his work imitative of any surface or texture, and will be shown later. Since the time of Bewick the black line has, however, been continued in this country, and been very highly developed.

The "Illustrated London News," established in 1842, familiarised the public to the beauties of wood engraving. In this periodical appeared the spirited drawings of Sir John Gilbert and the refined escape work of Birket Foster, both of whom might be said to have popularised book illustrations. At the same time were Millais, Pre-Raphaelites, and Fred. Walker, the first of whom drew a series of illustrations to the Parables which appeared in "Good Words," and which have since appeared in a separate volume.

The above-mentioned artists drew direct on the prepared block with pencil or pen and ink, and were careful to execute the shading in a way that the possibilities of the process of engraving would not be over-taxed. Many a pencil drawing, however, when printed, appeared in lines which were throughout darker than pencil work

could be. An instance of this were the political cartoons by Sir John Tenniel in "Punch."

The last phase of the wood engraver's art was entered on a number of years ago, when the American workers turned their attention to developing the possibilities of Bewick's practice. These men set themselves to facsimile any kind of original given them to engrave. The subject for reproduction might be an oil-painting, a water-colour, a charcoal or pencil drawing. They had it by means of photography printed on to the block; they turned out the work in such a manner that it seemed the original over again in monochrome.

This close mimicry was in turn hard pressed and perhaps overtaken by the photo process engraving, of which we have not yet possibly seen the full development.

## II. Intaglio or Copperplate Engraving.

As has already been pointed out, intaglio engraving is exactly the reverse in practice of wood engraving. The metals most commonly used are, or rather were (for it is almost a thing of the past), copper and steel, the former being the easiest to work, while the latter is the more durable.

These plates were very carefully prepared; to improve their quality in the earlier days the copperplates were hammered out upon metal tables, this giving them a closer grain and toughness than the rolling between heavy steel rollers practised later. The face was highly burnished, and on it the engraver started his laborious work, the method of proceeding being as follows:—A careful outline drawing in lead pencil was made on paper of the picture or design to be reproduced, the scale of reduction being arranged to suit the size of plate used. This sheet of paper was moistened between sheets of damp blotting-paper, and when sufficiently limp was removed, and laid face down on the burnished surface of the sheet of metal; the two together were then passed through a copperplate printing-press, when it was seen that the pencil lines had been transferred to the metal plate, of course giving a reversed drawing.

Now the engraver had a very delicate task before him, for while he had to make sure of the transferred drawing by tracing it over with a sharp needle, he had also to be very careful not to lose any part of the pencilling in the course of the operation. This done he would start with the graver to work out the picture in all its gradations and tones—a work involving much time and great patience.

This method of engraving had its origin, like wood engraving, in the fifteenth century; that is, the first impression on paper from an engraved plate can be traced to that time. This discovery is said to have been made by one Maso Finiguerra, a goldsmith and niello worker of Florence.

Towards the middle of the fifteenth century niello work was much practised in Italy, and especially in Florence. These *niellatori* were in the habit of engraving decorations on reliquaries, chalices, and other church properties. As the name will show, the designs were, when engraved, filled in with a black pigment which set with a black lustrous surface—hence the name. Finiguerra, it seems, was in the habit of filling in his designs with a soft mixture of oil and soot, so as to see correctly the effect his finished work would have before finally running in the permanent black enamel.

The story goes that Finiguerra laid one of those temporarily blackened pieces of work aside, and that someone carelessly laid a bundle of wet clothes on the top of it, only to find on removing them that the undermost article had taken an impression from the engraved work—possibly it was washing day. This is said to have suggested to Finiguerra the idea of doing as much with moistened paper. Be this as it may, that he did take impressions from his engraved work is proven by the discovery in the Paris Library in 1797 of a proof from a pax engraved by him and bearing the date 1452. Finiguerra seems not to have seen any further possibilities in the discovery than aided him in his work as a *niellatore*, and for twenty years after his discovery no engravings on paper were produced in Italy.

The first great Italian artist to dignify the art was Mantegna. He was certainly the most skilful and powerful of the Italian artists who at that time touched the graver. He worked with broad masses of shadow instead of remaining content with the somewhat outline work of that time. Other names might be mentioned, but perhaps it will be sufficient to single out those which mark a decided step forward in the history of the practice of the art.

The great art epochs might truly be said to have produced great

engravings, and this is certainly so in the case of Italy, for during the lifetime of Raphael the incomparable line engravings of Marc Antonio Raimondi were produced, just as in Germany those after Dürer were executed under his personal care; while much later in England the time of Reynolds might fittingly be styled the Augustan age of English engraving (in mezzotint).

Marc Antonio was a silver engraver, just as Finiguerra had been. This man is generally considered to have had his attention turned to picture engraving by seeing several prints by Dürer exposed for sale in Venice. Some he purchased, and to gain practical experience in the work he deliberately reproduced them line for line on metal. Having done so, he, unfortunately for his own good name, sold prints from his own plates. This forgery was detected by German merchants resident in Venice, who communicated on the matter with Dürer himself, who in turn raised a law action against them. This is said to have been the immediate cause of his leaving for Rome, where he attracted the attention of Raphael, himself an enthusiastic admirer of German engravers, having specimens of their work even of a date prior to Dürer, hanging in his atelier. Needless to say, Marc Antonio was employed by Raphael during his lifetime as his favourite engraver.

Great praise has been bestowed upon Antonio for the purity of taste and execution, together with the nobility of feeling apparent in his works, but we must remember that he was under the guiding eye of the great master himself, who is said to have furnished him with black and white drawings of the work he wished reproduced for his use during the actual engraving of the plate. Consequently, Antonio was not perplexed by the mysteries of colour and the intricacies of light and shade or tone. I am inclined to think that we have to thank Raphael in greater measure for these plates than Antonio who executed the work.

For a long time after his death the spirit and style of Antonio's work was the pattern, and was followed in all parts of Europe by line engravers. While the peculiar character of Antonio's work, which under the influence of Raphael was a linking of the antique with the living reality or of the form of the antique and the Christian in sentiment, the Dutch had gone on developing the style of their own countryman, Lucas van Leyden, which aimed at fulness of tone and close attention to light and shade, never going beyond its own immediate surrounding in search of types.

The next progressive move took place during the time of Rubens. This great artist, knowing the value and importance of engraving in increasing his fame and wealth, set himself to have his works published in engraved form. As models of style he seems to have looked to the Dutch on the one hand and to Antonio on the other. He employed the most skilful engravers he could find, and these he supervised as Raphael had done Antonio. This practice he continued during his life, and the result was a magnificent set of plates from his own works. The result of Rubens' influence on engraving was that careful modelling was fully developed, and instead of the minute detail of the German school, breadth was substituted, with greater attention to tone and colour than Antonio aimed at.

Vandyke, the pupil of Rubens, produced many very fine plates, principally portraits. These he executed himself. These works of Vandyke were not the work of the graver, but were produced by etching the entire work by means of an acid.

In this manner of work the procedure is as follows:—The sheet of burnished copper is coated with an acid-resisting coating called a ground, to which the pencil outline is transferred as in the case of an engraving. These lines are then scratched over, and the shading proceeded with in the same way by means of a needle set in a long handle, and used as one might use a pen or pencil. Of course these scratches lay bare the copper, and when the work is far enough advanced, the plate is subjected to the action of an acid, when the bare lines are eaten deeply into the metal. On removing the ground, the plate can be printed from just as an engraving is done. This process does not require the same practical skill so necessary to produce a good line engraving.

Heading this school of etching stands Rembrandt. He gave the full range of tone, and the full force of high light and intense shadow. Enough has been said of the Continental men; let us now turn our attention nearer home.

In England the earliest engraving of any historical value might be said to be the portrait of Queen Elizabeth engraved by William Rogers

from a portrait by Isaac Oliver. The first influence, however, left in England, was that of Rubens and Vandyke. Possibly this is to be accounted for by the fact of both having resided in England and been so handsomely treated by Charles I. Despite all the court patronage which Vandyke received, he is said to have been so sore pressed for money that he is declared to have consulted some soothsayer or magician.

It was during this reign that Faithorne produced a series of engraved portraits, considered to be the first really artistic native production. He as a Royalist fled to France, where he made good use of his time by studying the works of able engravers there, who were working in the spirit of the school of Rubens.

We all know the story of how mezzotint engraving was suggested to Prince Rupert, the nephew of Charles I., by seeing a soldier cleaning his rusted gun. This, no doubt, is a fable, but there can be no doubt that he has the honour of introducing the process into England. The credit of the invention of the process is generally assigned to Ludwig von Siegen, a lieutenant-colonel in the service of the Landgrave of Hesse-Cassel, who used the method in executing a portrait dated 1642; but of this latter. It was not, however, till the reign of George II. that native genius showed a real interest in the art of line engraving.

William Hogarth, whose name is of world-wide celebrity, engraved his own picture in a firm, clear style, similar to that practised then in France. His satires on the life of his time are familiar to all, from such series of engravings as the *Marriage à la Mode* and the *Rake's Progress*.

The pre-eminent names, however, among English line engravers are Sir Robert Strange and William Woollett. These men, by the great excellence of their work, placed England on an equal with Continental schools.

Strange was a native of Orkney, born in 1721, and learned his art in Edinburgh with one Cooper. On the outbreak of the '45 Rebellion he joined the ranks of the Pretender, and after Culloden he fled to France, where he, so to speak, relearned engraving by studying the works of men there who were carrying on the traditions of the school of Rubens. On returning to England, his talent was soon recognised, and he was largely patronised. Strange confined himself to figure work, principally of classical subjects, and during a visit to Italy, produced some of his finest plates after Raphael, Titian, and other masters.

Woollett, on the contrary, took up the branches of landscape and history. His skilful and intelligent labour brought him renown not only in England but on the Continent. Among his most celebrated plates are "The Fishery," "The Battle of La Hogue," and "The Death of General Wolfe." Woollett lived in London all his days, in a house in the neighbourhood of Rathbone Place, where, when he had finished a plate, he celebrated the event by firing a cannon from the roof of his house. There is a tablet to his memory in Westminster Abbey.

In the early years of the nineteenth century much fine work was produced in England by such men as James Heath, Anker Smith, Sherwin, and lastly the unfortunate Ryland, who ended an eventful life by being hanged for forging two bills on the East India Company.

Later on were John Landseer, father of the famous animal painter, Bromley, the two Cooks, John Burnet, celebrated as an art author, Charles Heath, and others.

The close of the eighteenth and opening of the nineteenth century witnessed what might be called the rise of a series of landscape engravers. This was the time when Scott by his poems and novels had drawn attention to the beauties of landscape, but it was the time of J. M. W. Turner, perhaps the greatest of all landscape painters. To engrave the reproductions of the latter called for a long line of names, not the least among them being our townsman Quaker Millar, for whose style Turner had a decided partiality. Often replying to publishers' inquiries as to whom he would advise to execute the work, "Oh, send it to the old Edinburgh Quaker."

Leaving line work now to deal with that of mezzotint, we come upon a manner of work which, if not so difficult and severe, is nevertheless more peculiarly national and popular, having been with but very few exceptions confined to England. In this style the engraver starts by working from black or dark to light. The forming of the grained surface on which to work is effected by means of a tool known as a rocker—a steel tool about two inches broad resembling a stump

el, one of its faces being grooved, and the cutting edge being red. This instrument is rocked or wriggled repeatedly over the face of the plate, until the entire surface appears covered by a red-like roughness. This surface is blackened with printer's ink, and the design scraped out by the engraver in all its variations of tone, the high lights being burnished. This department of engraving found its highest development during the reign of George

James McArdell, a native of Dublin, was one of the early men of the century who developed the artistic possibilities of mezzotint by excellent plates after Sir J. Reynolds, whose broad treatment of subjects made his pictures exceptionally suitable for this method of interpretation. Of McArdell Reynolds is declared to have remarked that even if the colours of his pictures faded his fame would be preserved by McArdell's engravings. This man introduced the practice of using vigorous etching to heighten the effect of mezzotint. Among his successors were R. Houston, John Greenwood, Edward Carter, John Spilsbury, Valentine Green, Jones Raphael Smith, and a host of others, the greatest, however, being Richard Earlom, who engraved after various masters, ancient and modern, and by the wide range of the subjects he undertook showed the wide resources of the mezzotint.

It was during this time that the Boydells had established their own firm, and a great proportion of the best prints of this period were the address of these famous publishers and engravers.

Other important mezzotint engravers of this period are Charles Turner and Samuel William Reynolds. The latter is reported to have been offered an important office in the court of George III., at a salary of £900 a year, but the offer was refused. The two names which close this great period of mezzotint engraving are David Lucas and Samuel Cousin.

He formerly engraved a series of landscapes after Constable which were justly renowned. One of the series, Salisbury Cathedral, was engraved at Constable's expense, and published by Hodgson, Graves, & Co., for the painter, 1837. After his sudden death in the same year it was sold at Foster's, and bought in for eighty guineas, hardly the price of two proofs at the present time. Last year, at Christie's, a set of Lucas' mezzotints after Constable's picture, "The Lock," brought ninety-two guineas, and a line engraving by Valentine Green of the same subject, namely, £237 5s., showing clearly how this vanished art is appreciated at the present day.

Cousin's figure work is familiar still, particularly his reproductions of Reynolds, but coming, as he did, after a long line of men who had done so much to develop and exalt the art, he to some extent repeats a repetition.

GEORGE M. AILLMAN.

## P.O.P.

### A PHOTO-ROMANTIC EPISODE.

By courtesy of the Editor of "Punch," we reproduce a contribution which appears in the current issue of our contemporary, and which may be commended for holiday reading. "Punch" for many years has shown itself alive to the fun which can be made from the technical operations and the "shop" expressions of photography. A few days ago we chanced to turn up the "Dark Room Soliloquy," and we all of us remember, we suppose, Du Maurier's skit on a suburban photographer, who begs the damsel of Eaton Square to think of "im."—Eds., B.J.P.]

They met at the conversazione of the local amateur photographic society.

"How delightful to be by your side again!" he murmured. "I have been trying to get you within my focal range all the evening, and have only just succeeded."

"That's the worst of those cheap lenses!" she retorted playfully, "they veiled her own brilliant orbs with her Thornton-Pickard-like lids. Do not trifle with me!" he exclaimed wildly. "Since our last meeting I have been stretched on the drying rack. I cannot eat. I have had my plates away from the exposure table untouched, and I have forgotten my actinometer number. There are films before my eyes, and I am hopelessly fogged, and my progress is merely a succession of black slides."

"But there! I have no desire to enlarge on my feelings, nor have

I the necessary apparatus at hand. Let us form ourselves into a group and retire behind this isochromatic screen. Here we can sit in camera, out of the range of the most brilliant view-finder."

"Miss Hypo, I have a positive declaration to make. For many months your latent image has been imprinted on my heart, and now the alkali of your sweet presence has accelerated its development."

"Oh, Mr. Pyro!" she exclaimed. "Did the image flash out rapidly?"

"No," he answered softly; "first the high lights, then the half tones, and finally the shadows."

"I am so glad you do not wear your heart on your sleeve," she whispered, "or it might have been over-exposed."

"Ah," he said, "it was almost a snap-shot, for do you not remember at our first brief meeting I had but time to take my cap off and put it on again?"

During this conversation they had been gradually approaching nearer to each other, with an almost imperceptible rack-and-pinion movement.

At length he murmured, in intensified tones, "Miss Hypo—Veloxia, if I may call you so, let me be your head-rest."

She blushed like a ruby lamp, and then gracefully reclined in profile against his rising and falling shirt front, looking like a delicate red chalk carbon print mounted on best white Bristol board.

"Oh, Mr. Pyro—George," she murmured sweetly, "mind my frilling."

"Frilling," he repeatedly dreamily, as though quoting from a text-book. "A ten-per-cent. solution of alum will prevent any frilling."

Then as his arm stole round her swing-back he asked her tenderly, "What useful photographic accessory do you resemble now, dearest?"

"A squeegee, George, dear," she answered, guessing right the very first time.

Suddenly, like a flash light, it was borne in upon Miss Hypo that Mr. Pyro was about to P. O. P. the question, and she remembered that it is not advisable to delay fixation unduly, so when, after thinking out the correct formula, George flung himself down at her feet on the lower joints of his bipod, her answer came in dulcet tones, like the trickling of gold chloride from a graduated measure. And it was not a negative.

## THE EASTMAN KODAK COMPANY.

### A YEAR OF INCREASED PROFITS.

THE annual report of the Eastman Kodak Company has been published, and shows the earnings of the Company to have advanced very considerably above the figure for the preceding twelve months. Following on the publication of the report, a sensational rise of twenty-two points took place on the Stock Exchange last week in the Ordinary shares of the Company.

The Ordinary shares, of which there are 250,000, have a nominal value of 100 dollars, or £20. They now stand at 210 dollars, or £42, and although nominally they are worth £5,000,000, their market value is £10,500,000.

The reason for the rise was the extraordinary success which has attended the Company during 1905.

The net profit for the year is £827,610. Of this £75,302 is used to pay 6 per cent. on the Preference shares, £483,085 to pay 12 per cent. on the Ordinary shares, and £268,144 added to the surplus account balance, which at December 31 last stood at £712,729.

An extra dividend of 2½ per cent. on the Common stock of the Company will be paid during the present month.

The annual earnings for the last eleven years show a record of steady progress on the part of the Company. They are:—

1895 .....	£49,656	1901 .....	£517,347
1896 .....	122,676	1902 .....	564,455
1897 .....	185,232	1903 .....	606,740
1898 .....	243,232	1904 .....	688,484
1899 .....	335,919	1905 .....	827,610
1900 .....	465,816		

Lord Kelvin and Sir James Pender represent the English shareholders on the board of directors.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between March 26 to 31 :—

REPRODUCING PATTERNS.—No. 7,250. Apparatus for the production of picture patterns by a photographic method. Neu Graphic Act-Ges, 18, Southampton Buildings, London, E.C.

APPARATUS.—No. 7,295. Improvements in photographic apparatus. Cesar Motti, 46, Lincoln's Inn Fields, London, E.C.

SHUTTERS.—No. 7,314. Improvements in photographic shutters. William James Bulgin and Arthur Edward William James, 60, Grange Road, Ashton-on-Mersey, Cheshire.

CINEMATOGRAPHS.—No. 7,403. Improvements in cinematographs. Ernest Reginald Law, 31, Bedford Street, Strand, London, W.C.

PHOTOGRAPHIC LENSES.—No. 7,661. Improvements in certain photographic lenses. Harold Dennis Taylor, Buckingham Works, Bishophill, York.

PRINTING APPARATUS.—No. 7,737. Improved photographic printing apparatus. Aaron Henry Howell, 38, Chancery Lane, London, W.C.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

REPEATING BACK.—No. 9,729. 1905. The invention consists in an improved repeating back for taking midget and stamp photographs, and is to enable a number of such small photographs to be taken upon a single plate in a short space of time and in such a manner that the various pictures shall be correctly placed upon the plate so that no overlapping can occur in the adjustment of the plate to the various positions in which it is exposed. An ordinary camera is employed, which comprises at its back vertical guides for the reception of a sliding framing which is adapted to receive in horizontal guides the dark slide and carries beneath the latter a focussing screen, so that by moving the frame up in its guides the screen is brought opposite the exposure aperture in the camera back, and by sliding the dark slide in the horizontal guides a fresh portion of the plate is brought into position for exposure. There is provided in connection with the camera, a reversible dark slide so fitted that a number of pictures can be taken upon different portions of the same plate, and not two only as heretofore; also an automatic mechanism for accurately adjusting the dark slide and for indicating to how many of its possible positions the dark slide has been adjusted, so that it is impossible to make a mistake in the counting of the number of exposures even when working very quickly. Upon the back board *a*, which may be of such dimensions as to fit in the back of a camera of any desired size, a carrier or adapter *b* is mounted by means of the circular guide and guide way *c*, in order to allow, in the well known manner, of securing pictures either in the upright or horizontal positions. This rotatable adapter *b* is fitted with guides *d* along its vertical edges, such guides being preferably constituted by L shaped metal strips as shown. Between the guides *d* is introduced the sliding frame or dark slide carrier *e* in such a manner as to be slidable up and down in the guides *d*, the carrier *e* being fitted with horizontal guides *f* for the dark slide *g* to move in. A sensitised plate *h* is placed in the dark slide *g*. Along each edge of the dark slide *g* is formed a number of inclined notches *j*, preferably by fitting strips of brass *k*, having the notches already formed in them, to the said edges. The dark slide *g* is formed so that it can be inserted into the guides with either of these edges uppermost. A driving pawl *l* is adapted to engage with one of the inclined notches *j* during each upward sliding movement of the carrier *e*, and to then move the dark slide in the guides *f* a distance equal to the distance separating one notch *j* from the next, such distance being equal to the width of the desired pic-

ture, thus an exposed portion of the sensitised plate is automatically moved away from the exposed aperture and a fresh portion of the plate is brought opposite such aperture. The automatic movement may be effected by carrying the pawl *l* upon a spindle *m* rotatably mounted in a block *n* slidable in a guiding frame *o*.

Fig. 1.

To the spindle *m* is fixedly connected a lever *p* which is fulcrumed at *q* to the adapter *b*. It will thus be seen that as the carrier *e* is moved upwards from the position shown in the drawings, the lever *p* will be turned about its fulcrum *q* and will move the block *n* from the right hand end of the guide *o*, in

Fig. 2.

which position it is seen in Fig. 1, to the left-hand end of the guide, Fig. 1, thus the pawl *l*, being in engagement with the second notch from the left-hand end of the dark slide *g* moves the latter to the left and upon the next descent of the carrier the block *n* and pawl *l* will be moved to the right and the pawl

will move into the third notch. An exposure aperture *r* in the back board *a*, a similar aperture *s* in the adapter *b*, and a similar aperture *t* in the carrier *e* are in alignment when the carrier *e* is in its uppermost position, that is to say when it rests against the stops *u*. In this position an exposure can be made by drawing back the cover *v* of the dark slide and by pressing together the knobs *w*, *x*, which later movement imparts a pull to the wire *y* causing the lever *z* to turn and to oscillate the wings 1, 2, of the shutter in the well known manner. The operation is as follows:—The focussing having been accomplished and the carrier *e* having been moved down to the position shown in Fig. 2, the cover *v* is drawn out and the shutter operated so that an exposure is made upon that portion of the plate shown in dotted lines in Fig. 1. The cover *v* is then pushed home again, and the thumb being applied to release the spring detent 13 the carrier *e* is moved upwards in its guides *d* until arrested by the catch 3. During this upward movement the lever *p* has caused the pawl *l* to move the dark slide to the left hand, Fig. 1, to the extent of the distance between two adjacent notches. The focussing screen 4 may now be observed, and when the fresh adjustments have been made the carrier *e* is moved downwards into contact with the stops *u*, the pawl *l* being meanwhile oscillated in the manner described so that the pointer 8 moves on from the numeral "1" on the disc to the numeral "2" when the fresh portion of the plate can be exposed. If now a horizontal or so called "landscape" picture is desired in place of the ordinary upright picture, a suitable clamp or catch 15 may be released and the adapter *b* be revolved upon the back board *a* by means of the circular guide and guide away *c*. After the third picture has been taken upon this half of the plate, the dark slide *g* is taken out of its guides *f* and is re-inserted in an inverted position, that is to say, so that the half of the plate now seen uppermost in Fig. 1, will be brought to the lower position and into alignment with the exposure apertures and the pointer 8 then points to the lower set of numerals upon the disc 6, and when the numeral 3 in such lower set is reached it is at once seen that the whole of the plate has been exposed. George Thomas Bayley, 3, Union Street, Stonehouse, Devon.

**SENSITISERS.**—No. 16,227, 1905. The claims are: (1) For the manufacture of blue colouring matters of quinoline group by the action of an alkali, in presence of formaldehyde (or of a substance yielding formaldehyde) on a salt of an alkyl-quinolindinium base, either alone or mixed with a salt of an alkyl-quinolinium base, and (2) for photographic emulsions sensitised with these dyes. As an example of the mode of production, the following is given by the patentees. Thirty parts of quinaldine-etho-iodide may be dissolved in 150 parts of hot pyridine, and 10 parts of formaldehyde of 40 per cent. strength and 10–15 parts of soda-lye of 16 per cent. strength are added; the whole may then be heated to boiling for some minutes. When cold the product separates partly as crystals of metallic lustre, and may be completely precipitated by addition of about 500 parts of water. It may be washed with water and recrystallised from alcohol or methyl alcohol. The colouring matter is dissolved by alcohol to a blue solution and its properties correspond with those previously described. The invention includes the use as raw materials of salts of the homologous and substituted alkyl-quinolindinium and alkyl-quinolinium bases as well as the salts of the simple alkyl-quinolinium and alkyl-quinolindinium bases. The colouring matters obtained are also blue, green-blue to blue-green, and have the same properties as those described above. For the formaldehyde may be substituted such compounds as either readily yield formaldehyde or may be easily transformed into formaldehyde, for instance, anhydro-formaldehyde aniline and its homologues, besides methylal, ethylal, and the like. The process is not essentially changed when these are used. The colouring matters prepared as described above from alkylhalides are themselves halides and may be treated with salts of metals forming insoluble halides, such as silver salts, in order to convert them into salts in which other acid radicles take the place of the halogen, thus for instance, with silver nitrate the easily soluble nitrate may be obtained. The chief application of these colouring matters is in photography, as they render silver halide emulsions manufactured in any known manner, highly sensitive to red light. O. Imray for Farwerke, vormals Meister Lucius and Brünig, Hoechst a/Maine, Germany.

The following complete specifications are open to public inspection before acceptance under the Patents Act, 1901:—

**SCREENS.**—No. 6,881, 1906. Optical screens for photographic and printing purposes. Smith.

**PRODUCING PATTERNS.**—No. 7,250, 1906. Apparatus for the production of pictures, patterns, etc., by a photographic process. Neu Graphic Act. Ges.

**CINEMATOGRAPHS.**—No. 7,403, 1906. Cinematographic apparatus. Law.

## Photo-Mechanical Notes.

### The Reproduction of Chinese Whites.

In the paragraph on this subject last week the filter requisite to enable Chinese whites to be photographed satisfactorily was stated to be 10 per cent. quinine sulphate. This was a printer's error. The amount should be 1 (one) per cent. only.

### The Bolt Court School Report.

There are thirty-three plates accompanying this report, five photogravures, eight lithographs, one collotype in colour, and the rest line, half-tone, and three-colour blocks. The latter seem to be of steadily improving quality. The photogravures are also good, some excellent subjects being reproduced. We suppose the block work is quite up to the average, but many of the subjects are not striking, and there is an absence of any particularly educational or experimental ones, except perhaps in the case of two plates reproducing sketches for book-bindings. These are effective enough. Many of the reproductions are from originals by students in the design or art classes, some of the designs for book decoration being decidedly good.

### Photography and Map Reproduction.

When a section of a map has been required to be reproduced on an enlarged scale it has usually been the custom to do it by means of the pantograph. But map makers are finding that it is more expeditious and more economical to photograph the original map, then enlarge on to bromide paper (generally a gaslight paper) and then trace over the enlargement. Plan reproduction establishments often employ girls to do tracing, as they find them reliable, and their labour not so expensive as men's.

### Retouching Screen Negatives.

Provided the half-tone negatives are not varnished, the dots may be strengthened by blacklead. If only a small portion is required then a soft pencil is used, if a large area such as a sky, the lead may be rubbed on by means of a pledget of cotton wool or a stump. The lead will be found to adhere to the tops and sides of the dots only, and if done correctly will not touch the centre of the spaces between the dots. One would think it unnecessary to resort to this practice at all, nevertheless it is the rule at one large Continental establishment, and almost every negative is so retouched.

**EDUCATION by Photograph.**—By courtesy of the Board of Education there is now on exhibition, at the Bootle Museum, a series of choice photographs of Westminster Abbey. The pictures, which are exceptionally fine examples of the photographer's art, number sixty-eight, and are comprised in some thirty-four frames. The collection will remain on view until the middle of June next, and may be inspected by the public free of charge.

**A COMBINED Outing of Societies.**—Messrs. Walter D. Welford (president) and T. Mitchell (hon. sec.) of the South Essex Camera Club, have issued a letter to the societies that attended last year's event. They are anxious to hear from some society willing to organise the outing for 1906, and with a view to this, for opinions as to date and promises of support, they ask the hon. secs. or a representative to attend an outdoor meeting, or hon. secs. outing, at Wanstead Park on Saturday afternoon, April 21. Meet at Pavilion at 3.30 p.m.

## New Books.

**Die Retusche von Photographien.** By Grashoff-Loescher. Berlin: Gustav Schmidt. Price, 2s. 6d.

This work, originally written by Grashoff, has been revised by Herr Fritz Loescher. It is hardly necessary to say much about it, as it has reached its tenth edition—a fairly conclusive proof that its teachings are satisfactory. The chief alterations, however, from the previous edition are that the chapters on negative and print retouching are practically re-written, and a new chapter on the working up of landscape negatives and the making and working up of enlarged negatives for gum printing has been added.

**Die Farben-Photographie.** By Dr. E. König. Berlin: Gustav Schmidt. Price, 2s. 6d.

Since the first edition of Dr. König's work was written in 1904, considerable advances have been made in the sensitising of plates, and this has entailed practically an entirely new chapter on this subject. Other new matter has been added in the shape of full working instructions for most of the direct methods of colour photography, including the Lumière, Sanger-Shepherd, Selle, Pinatype, and Pinachrome processes. This last, we note, is stated not to give permanent results, and therefore is no longer in practice. There is, however, no mention of any photo-mechanical process, the book being a practical treatise on the processes, examples such as were shown at the recent exhibition held in our offices.

The direct processes such as Lippmann's and Becquerel's are briefly treated of, and a very complete section deals with the additive methods by optical synthesis, and the making of a chromoscope.

**Photographisches Unterhaltungsbuch.** By A. Parzer-Mühlbacher. Berlin: Gustav Schmidt. Price, 3s. 6d.

This is the second edition of a work which can be best described as a reference book for amateurs, for in its 237 pages will be found a brief description of almost every branch of photography from the making of spurious ghosts, caricatures and silhouettes, to X-ray work and colour photography. Considering that there are no less than seventy-six subjects treated of, it is obvious that the information given is in no case complete, still there is something to be found on most subjects, and here and there one does find references given to complete monographs on the subjects. The book is very fully illustrated with half tones, mostly from actual specimens of the processes made by the author.

## New Apparatus, &c.

**Anachromatic Lenses.** Made by L. Turillon (late Darlot), 99, Rue la Fayette, Paris.

Since the appearance of the contributions by MM. Puyo and de Pulligny, dealing with these new lenses of their design, we have been in receipt of several of the actual lenses constructed by M. Turillon, and we shall probably be consulting the wishes of many of our readers in placing before them a description of the instruments. This we do here, after the optical examination of one example of M. Turillon's manufacture, but the optical properties of the lenses demand a more extended consideration than can be given them in this place, and we discuss them in an article on another page. The anachromat outfit, of which we are writing, is supplied as a set of four lenses, all fitting the same mount and giving objectives of identical focal length suited for different purposes. The set gives lenses of 12 inches focal length put forward for use on a 7 x 5 plate, each glass is of large diameter, about 2½ inches, and each is a single uncorrected lens of crown glass. The mount is of the ordinary rack and pinion portrait type, but, unlike the ordinary portrait lens, the rack is not used for focussing, but for the chromatic correction of the objective. The diaphragm scale on the mount is marked with the numbers 1, 2, 4, 8, 16, and 32, representing the relative exposures. No. 1 is  $f/5.5$  with the doublet,  $f/5$  with the plano lens of the set in front of the stop, and  $f/6$  with either the plano or meniscus

lens behind the stop. The whole lens weighs 2 lbs. 6 oz., and has a 3¼-inch flange, hence a camera of strong build, and with large bellows is necessary, but a very great extension is not called for. The double extension square bellows camera of "studio" pattern is suitable for the purpose.

The mount bears the well-known name of Darlot, which is a sufficient guarantee of excellent workmanship and finish. One or two small matters are, however, worth drawing attention to. The stop marks now come under the jacket and are invisible when the lens is adjusted for focussing. If marked on the other side of the diaphragm slot this trouble would disappear. Again, the book on "Artistic Lenses" continually suggests the use of such apertures as  $f/6$ ,  $f/6.3$ ,  $f/6.5$ ,  $f/7$ , etc., but the two largest stops provided have exposure values of 1 to 2 only, and no intermediate stops are given. We suggest that an additional mark representing an exposure value of 1½ would be an advantage. This would correspond to a stop of from  $f/6$  to about  $f/7.3$ , with the different combinations, and would be distinctly useful in attempting to follow the advice given in the book.

The whole outfit is sent out in leather case and costs 85 francs. The lenses, however, can be obtained of suitable sizes to fit any focussing portrait mount, and thus the whole can be obtained at a low figure, although the price of the complete set cannot be called excessive.

**A New Developing Dish.** Made by Taylor, Tunncliffe and Co., Ltd., Eastwood, Hanley, Staffs.

The makers of this new pattern of dish recommend it primarily on the ground that the plate can be developed, fixed, and washed in it film downwards. We are not entirely of their view in regard to the alleged advantages of this facility, though we have convinced ourselves in several ways that gelatine plates can be so handled in the dish with impunity. The inverted position is possible owing to the special construction of the bottom of the dish. It is formed of four slightly raised inclines leading from the centres of the sides of the dish, and meeting in the centre of the dish. As a result the plate rests on four points, and it is the easiest matter to remove it from the developer, pressure on one corner raising that opposite and thus permitting the operator to withdraw it with the finger. As we have said, we have proved to our own satisfaction the absolute practicability of working with the plate-film down, (1) by developing an exposed plate; (2) by fixing an unexposed and undeveloped plate, and (3) by bleaching a negative. In each case we found the action to take place uniformly over the entire surface, the four-minute points of contact of film and dish being noticeable only in the case of the fixation experiment by the slightly longer time necessary to remove the last traces of silver bromide from these parts. This, however, may be regarded as a kind of signal that the whole of the plate is perfectly fixed. The advantages on which the makers dwell are: Economy of developer, facility of control by observing the back of the negative, and protection of gelatine surface from dust; but we believe that these points are quite minor ones, and that the convenience of the dish for the manipulation of the plate in the usual way supplies quite sufficient reason for drawing prominent attention to the new introduction.

## CATALOGUES AND TRADE NOTICES.

A new list of Messrs. Staley's is descriptive of the many patterns of hand and hand-stand cameras supplied by this house. It calls for mention as a well-illustrated catalogue, and for the fact that Messrs. Staley make a specialty of fitting genuine Bausch and Lomb shutters to all kinds of cameras. The list is sent from 19, Thavies Inn, London, E.C., on receipt of a penny stamp.

MESSRS. Wellington and Ward have issued a new and enlarged edition of their booklet, "Notes on the Wellington Specialties," a guide in brief to the use of the various well-known "Wellington" manufactures. The new edition is brought up to date by notes on light filters for field and dark-room use on the employment of "Iso Speedy" plates, and by the addition of some very useful notes on chemicals, a study of which would prove the solution of many alleged mysterious problems. The booklet is offered free to any bona fide user of photographic materials.

## New Materials.

**Goldona** (Self-Toning Paper). Made by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.

The new brand of self-toning paper is happily named, inasmuch as it expresses in a word Messrs. Griffin's contention that in their new product it is the gold which actually does the toning, and that this characteristic, among others, of the paper should mark it out for a favourable reception. As regards manipulation there is a gratifying simplicity of information to be given. The printing is done a shade deeper than usual, and the copies are then placed in a hypo. bath of 2 or 4 oz. per pint, the stronger bath being employed for darker tones. If preferred, the prints may be washed before passing to the tone-fixing bath, a practice which is to be recommended on a score of permanency, and one which, in our not very lengthy experience of the paper, yields prints of a tone one or two shades warmer than those made under identical conditions but without the preliminary wash. In these respects "Goldona" has all the merits of papers of its class. Like them it is the embodiment of necessary simplification reduced to its simplest terms. The paper also possesses a very noteworthy feature that the range of tones obtainable in a print is a very wide one, with the result that we have deep shadows free from the choked-up appearance which a less perfect product would exhibit. For this reason, in particular, "Goldona" is likely to be esteemed among printing papers. The variety of tone produced by the single fixing operation is good, and in all of them, as we find, the retention of the finer half-tones is one conspicuous virtue of the paper. We understand that Messrs. Griffin have launched a scheme of free distribution of samples to amateurs, but, doubtless, any inquiries addressed to them at Kingsway, London, by professional photographers will receive every attention.

**Bromona** (Bromide) Papers. Made by Ilford, Ltd., Ilford, London, E.

In addition to their series of bromide papers, the Ilford Company have provided photographers with three distinct varieties of paper suitable to the usual development and toning processes. These varieties of "Bromona" are:—

- Grey Medium—Brand G.
- Cream Rough—Brand C.
- Aquamarine Canvas—Brand A.

This selection is one which has particularly interested us in offering new facilities to photographers in the rapid, certain, and economical production of prints from both landscape and portrait negatives. The papers bear, so far as our observations go, a bromide resemblance of the usual kind; it is in the support that the differences are, and the novel character of the results obtainable is observable, especially in the case of the "Grey Medium" and "Aquamarine Canvas" brands of Bromona. Both these are tinted papers, the former being a pale bluish grey, exceeding to a minute extent what should consider neutral. The tone in our eyes has appreciably more colour in it than can be fittingly described as "grey" simply. The surface of the two papers is very different. Brand G ("Grey Medium") is not a smooth paper, but the coarseness of its surface is not at all pronounced. We should not consider it by any means too rough for prints of normal subjects no larger than 5 x 4. The Aquamarine, however, the "Aquamarine Canvas," possesses a pronounced "pebbly" texture, and is not advanced, we naturally assume, for attempts to be closely scrutinised. For larger work, whole-plate and upwards, prints made upon this paper present a very agreeable appearance, and the user of this and the "Grey Medium" paper will be long before he discovers that he has in them the power to employ negatives for enlargements which otherwise he would be compelled to reject, except by resort to methods involving series of micro-gymnastics out of the question in practical photography for commercial purposes. The tinted ground of the paper of itself substitutes contrasts to an extent which only requires to be seen by comparison with a print from the same negative on ordinary white or cream paper. Moreover, in the case of the A paper, the "pebbly" irregularities of the surface break up masses of black shadow in a way which immensely ameliorates deficiencies of the negative. As regards the C or "Rough Cream" brand of "Bromona," we

have these same opportunities for imparting a tone to the photograph, but the character of the paper in this instance makes for brightness and brilliancy rather than for the more subdued effects to which the two previous varieties lend themselves. The grain of the C paper, however, is coarse enough to remedy detailless masses of shadow up to a reasonable degree, and for this reason should be a popular paper for enlargements of considerable size. In conjunction with the sulphide toning process, to which we find it to be agreeably amenable, it should be capable of giving extremely rich and handsome effects.

The impression left on the mind after a considerable batch of prints on these new papers had been completed was that in placing them on the market Messrs. Ilford, Ltd., are adhering to the policy, as evidenced recently in the "Amauto" plate, of substituting for the haphazard methods of the dark room the provision of materials by which results are obtainable with a tithe of the trouble and with certainty of repetition. In place of tinkering with a bromide print by complex solutions to diminish the excessive contrasts, you accept the facilities which such papers as these offer, facilities which are standardised through the large way in which they are produced and which must inevitably pay the photographer better than the old-fashioned recipes for doing the same thing by a roundabout process.

We have only to add that the prices of "Bromona" are based on 1s. for twenty-four quarter-plate pieces.

Under the name of Tylo a new developing agent has been submitted to us by Mr. A. Leblanc, representing a French firm of chemical manufacturers. "Tylo" belongs to the rapid phenolic class like metol, to which it bears considerable resemblance in action. Using the general formula as given on page 953 of the Almanac, 1906, we find that the image makes its appearance very rapidly, and that density is easily obtained with prolonged development. Colour of the image is black, and bromide has but little influence on it. With potassium in the place of sodium carbonate, the developer seems yet more energetic. It may be combined with either hydroquinone or pyro, and for the former the following is the proportion suggested:—

Tylo .....	3 parts.
Hydroquinone .....	7 parts.
Sodium sulphite .....	100 parts.
Potassium carbonate .....	60 parts.
Water .....	1000 parts.

This is a very energetic developer, giving full contrast and great density in the high-lights with prolonged development. It can also be used for bromide paper, with the addition of potassium bromide, and gives clean whites and good blacks. From a brief comparison with metol in plain aqueous and sulphite solution, Tylo seems to possess rather better keeping properties, for in an open dish there was markedly less colouration in a given time.

### FORTHCOMING EXHIBITIONS.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 16-21.—Redcar Photographic Society. Entries close April 9. Secretaries, W. H. Taylor, Esplanade, and J. M. B. James, 4, Elton Street, Redcar.

April 18 to 20.—Southend-on-Sea exhibition. Hon. Sec., J. Archer, 24, Ashburnham Road.

April 18 to 21.—Bolton Amateur Photographic Society. Secretary, T. W. Cross, 27, Latham Street, Bolton.

April 20-21, 1906.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.

April 27-May 27.—Northern Exhibition (Manchester). Sec., G. M. Morris, 9, Chandos Road, Chilton-cum-Hardy, Manchester.

May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
13.....	Aberdeen Amat. Photo. Assn.	"Printing Papers" Mr. Anderson.
16.....	Stafford Photographic Society...	Annual General Meeting.
16.....	Catford & Forest Hill Ph. Soc.	"Peeps at the Peak." Mr. W. D. Dawes.
16.....	North Middlesex Photo. Soc. ....	Excursion to Rochester and Aylesford.
16.....	Oxford Camera Club .....	Photography Prize Slides.
16.....	Wandsworth Camera Club .....	"Architectural Photography."
17.....	Bristol Photographic Club .....	Amateur Photographer Prize Slides.
17.....	St. Helens Camera Club .....	"Hand Camera Work." Mr. K. F. Bishop.
17.....	Darlington Camera Club .....	"Titles and Titling." Mr. R. W. Chapman.
17.....	Warrington Photo. Soc. ....	"Trimming and Mounting." Mr. D. S. Birrell.
17.....	Hackney Photographic Society	"The Page Croft Pigment Paper."
17.....	Blaigowrie and Dis. Ph. Assn.	"A Night with the Federation Portfolio."
17.....	Cardiff Windsor Amat. Ph. Soc.	Competition Night.
18.....	Redhill and District Cam. Club	"A Chat on Photography in Natural Colours." E. E. and C. Robinson.
18.....	Everton Camera Club .....	Members' New Lantern Slides.
18.....	South London Photo. Society .....	"Marine Photography." Mr. F. J. Mortimer, F.R.P.S.
18.....	Redcar and Coatham Ph. Soc.	Yorkshire Photographic Union Portfolio.
18.....	North Middlesex Photo. Soc. ....	"Bromide Enlargements." Mr. H. W. Fincham.
18.....	Cricklewood Photo. Society.....	"Birds and Beasts of Prey." Mr. R. L. Woolcott.
18.....	Tunbridge Wells Ama. Ph. Assn.	Members' Lantern Slides.
19.....	London and Prov. Photo. Assn.	"Matted Paper." Mr. L. Thornton.
19.....	Southport Photographic Soc. ....	Annual General Meeting.
19.....	Burton-on-Trent Nat. Hls. Soc.	Exhibition.
19.....	Darwen Photographic Assn.....	Members' New Slides.
19.....	Liverpool Amateur Ph. Assn.....	Auction Sale.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, April 10. A paper by W. B. Ferguson, K.C., M.A., on "A New Method of Calculating the Times of Development at Various Temperatures," was read by the author. It was a description of a simpler method than that printed in the B.J. March 31, 1905, p. 249. In place of an H. and D. machine, a carefully calibrated graded screen was used, and a quarter-plate exposed to a standard candle, the exposures being thus from 2 to 50 c.m.s. This plate was cut into four strips, and two were developed for five and ten minutes respectively at 8 deg. C. with the H. and D. standard pyro-soda used at half strength. By measurement in the photometer the development factors were obtained, and thence K as the velocity of development, and  $\gamma \propto$  the density-giving power. The other two strips were developed in like manner for 3 min. 18 sec. and 6 min. 36 sec. respectively at 18.5 deg. C., and the above constants also determined in the same way. From the results thus obtained it was easy to calculate the necessary duration of development to produce any development factor at a given temperature, for if the times necessary to produce the same development factor at  $x$  deg. C. apart are known, the temperature coefficient can be obtained by subtracting the logarithm of the lesser time from the logarithm of the greater time and dividing by  $x$ : the result will be  $\log. b$ . Taking, then, the time necessary to produce, with a given plate and developer at a given temperature, a given development factor, it was only necessary to subtract from the logarithm of this time 2  $\log. b$  to obtain a table which would give the necessary times of development at every 2 deg. In conclusion, Mr. Ferguson stated that in practice the above method is not so long as might be thought, and expressed a hope that plate manufacturers would see their way to issue with each batch of emulsion a table of times of development at different temperatures for the particular developer recommended by them.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting on Thursday, the 5th (Mr. W. Hart in the chair), Mr. E. Morgan demonstrated the Richmond Self-Toning paper. It was, he said, his object to try and convince the meeting that it was possible to make a great saving in the time of silver printing, and that without in any way decreasing the permanency of the prints.

P.O.P., he thought, would hold its own in the future as in the past—at least, until we obtained another process that would give the same delicacy. A continuous improvement had gone on during the past few years in plates, cameras, lenses, and developers, but silver printing had been allowed to almost stand still. Makers of silver papers had of recent years tried to do away with separate toning baths by adding gold to the emulsion. As all silver papers contained a free acid, the putting of such papers direct into an hypo bath must produce sulphur toning, and this was without doubt a step backward to the old days when such procedure was common. The Richmond paper did not depend upon its free acid for the toning, as it was recommended to first wash the print for at least five minutes—longer being even better—and then to fix for ten minutes in a bath of 3 oz. hypo to 20 of water, adding thereto 1 drachm of soda bicarbonate. Thus there was not any decomposition of the hypo or sulphur toning. The new medium, agar-agar, of the paper was not liable to crack or curl, it had a high setting point—that of 90 to 98 F.—and it might be worked successfully in a temperature of 150 deg. without any harm. It could be dried by heat—in fact, Mr. Morgan dried prints during his remarks by the aid of a spirit lamp, and one could see the steam arising from them. Blistering or frilling could not for this reason be met with, but the prints could not be squeezed. The tones could be varied at will by the length of time in the fixing bath, and for warm tones the strength of this could be reduced to 2 oz. in 20 oz. Prints after treatment in an acid bath might also be first toned in a platinum bath composed of potass. chloroplatinite 15 gr., water 2 oz. Take 2 drachms stock solution, make up to 10 oz., and tone, wash for not less than fifteen minutes and fix. Upon being placed in the fixing bath the prints at once toned to a good black, and the tones were not obtained at the expense of permanency. Mr. Haddon asked if agar-agar, when kept in solution, was, like gelatine, liable to decomposition. When P.O.P., washed, toned, and fixed in separate baths, afterwards darkened, was the darkening caused by sulphur? Again, the gold in the paper was to tone it when fixed, but what became of the gold in the high lights? Was it dissolved in the hypo bath, or left in the paper. If left in the paper, was it not liable to damage the print afterwards? Mr. Morgan replied that he had not tried the keeping qualities of agar-agar in solution, but he thought that any solution so kept would ferment, hence he thought that it would be dangerous to so keep it, though up to the present they had not found any alteration. With regard to the sulphur left in the prints, he thought that was overcome by making up a new fixing bath for each batch, and so the hypo would not get decomposed and cause sulphur to deposit. His theory as to the gold in the high-lights was that it became insoluble when exposed to light, hence it was soluble in the high-lights and not in the shadows. He thought it was washed away in the first washing. Mr. Haddon proposed, and Mr. Teape seconded a vote of thanks to Mr. Morgan, which was heartily carried.

CROYDON CAMERA CLUB.—The President, Mr. W. H. Smith, last week gave a demonstration on "Odds and Ends," which, if not in its entirety photographic, most certainly lost nothing in interest on that account. First came "Sanzol," the new slow-acting reducer, its properties appearing to lie midway between ferricyanide and hypo, with its tendency to increase relative contrasts, and ammonium persulphate, so apt at times to unduly flatten the image. A negative was successfully reduced before those present. The lecturer next described an ingenious method evolved by him for printing-in cosway borders, and equally useful for other forms of combination printing, which does not admit of condensed description. Minor workshop practice was then dealt with, and the tips and wrinkles imparted were so many and varied that it would require a long list merely to enumerate them. One experiment in the nature of "a pleasant surprise for the children" created some fun, and as it has never been described, is worth mentioning. Mr. Smith showed an empty tin with the lid off, it being, as a matter of fact, a medium-size platinotype tin. In the bottom of the tin a small hole was punched, and about two-thirds up a similar hole had been made in the side. The tin was then inverted over a gas jet, filled with gas, lighted at top, and then placed in a bowl of water, the hole in the side of the tin standing just clear of the water. He then genially said that as the gas burnt away the air

ering through the side aperture would at a certain point form explosive mixture, when *up* would go the tin. On hearing this explanation several members in its immediate vicinity promptly shifted back in order to obtain a better view, and all y attentively watched the dwindling flame; the chief point of interest apparently being not so much the manner in which the might go up, but rather the precise direction in which it would e down. Lower and lower, but very slowly, sank the flame, il it almost disappeared, turned green for a second, then, with a ng, the fin shot up, duly recorded itself on the ceiling, and ingly returned close to the starting point.

**BRISTOL PHOTOGRAPHIC CLUB.**—At the last meeting, Mr. F. Wilkey e a practical demonstration of printing in platinotype, and in scribing the ideal negative required, he stated that the deepest adows should be slightly veiled, in order to avoid "bronzing" in print. Another point emphasised was the influence of sodium hosphate in the developer upon the contrasts, the larger the portion of this salt the greater the contrasts. For normal negaes the following developer was specially recommended, viz., assium oxalate, 16 oz.; sodium bi-phosphate, 4 oz.; water, 112 oz. ile for weak negatives the sodium bi-phosphate could be increased 6 oz.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—At the annual meeting d April 2, 1906, at Collyer Hall, Mr. C. H. Oakden, F.R.P.S., was ected President for the year in place of Mr. J. T. French, whose ar of office had expired. Mr. C. Churchill, F.R.P.S., who for ny years has been the much valued Treasurer of the Society, found elf compelled to resign, and Mr. W. Calder Marshall, F.C.A., s elected in his place. Mr. C. Churchill and Mr. H. Creighton cket were each unanimously elected to the position of Vice- sident of the Society.

**REIDHILL AND DISTRICT CAMERA CLUB.**—At the meeting, on April 4, . G. E. Frisby gave a very interesting lecture on photography as plied to natural history. Mr. Frisby exhibited slides illustrating a life history of insects and their habits, and also specimens of iversal rare forms found in this and other countries. He also showed ographs of fossils, shells, etc., showing the wonderful way in hich their details and peculiarities can be portrayed by the camera.

## Commercial & Legal Intelligence.

**A CARDIFF CANVASSING CASE.**—Last week Edward Kelsey was arged on remand at Cardiff with having, by means of false prences, obtained 9s. from his employer, Mr. Clement Stone, photog- apher, 2, Guildford Crescent. Mr. Samuel, for the prosecution, id prisoner was employed to canvass and collect orders for the largement of photographs. Upon all orders obtained he received er cent. commission, in addition to nominal wages of 10s. a week, hich was passed upon proof that the orders were satisfactory. risoner also received from every customer a shilling deposit. He ve a receipt for the shilling, took down the name and address e customer from whom the order was taken, and also wrote e name and address, together with the necessary particulars for the largement, on the backs of the photos. On Saturday, February 24, went, as usual, to the shop, and handed in five photographs, all hich were found to be fictitious orders. Prisoner was only arged, however, in respect of two of those orders. He succeeded, owever, in obtaining the commission on the two orders. He was nt entitled to the commission until the orders had been proved e satisfactory, but upon his plea that his wife was unwell, and at he himself was recovering from a severe illness, prosecutor was duced to pay the money in advance. Prisoner received 17s. 6d. ogether, which was equal to 10 per cent. on each of the five rders, less the 5s. deposits. For the defence, Mr. Harold Lloyd bjected witness to cross-examination, a large portion of which e may quote, as reported in the "South Wales Daily News." re you the Free Enlargement Company? asked Mr. Harold Lloyd.— o. Have you anything to do with that company?—No. Were ou complainant in a case at Caerphilly Police Court a few weeks go?—Yes, I was. Was it called the free enlargement case?—I don't

know what it was called. Did the man beat you with a free enlarge- ment? That's what you summoned him for? Yes. Why did you say you had nothing to do with "free enlargement"?—I have not. It has nothing to do with the case. I daresay not. Was it the prisoner's duty to go about to various people in the valleys and to take with him a large picture?—Yes. When the pictures were returned to you they were returned for the purpose of being enlarged?—Yes. Well, I will leave out the word "free." I don't sup- pose you do anything free. Is it an enlarging business? Is it the word "free" you object to?—Yes. Your travellers are told to tell the various people that they would have a large photograph free of all cost?—No. I suggest the reason is that in this swindling process a large number of photographs are refused?—No, it is a lie, and I ask you not to use the word "swindle." Mr. Harold Lloyd: I use the word advisedly. Continuing, Mr. Lloyd asked: Is it a fact that a large number of orders are taken by your travellers, and when people come and ask you to carry out the work you refuse to do it?—No. You carry on business in the Rhondda Valley?—Yes. As the American Photograph Company?—Yes. Also in the Rhymney Valley?—No. Not as the Public Benefit Photograph Company?—No. A man pays half the rent of the shop. Do you give instructions to your agents to give different names in different valleys?—Not at all. Further examined, witness said that prisoner's wages ranged from 30s. to 40s. a week. "Sometimes 7s. 6d.?" asked Mr. Lloyd, in insinuating accents. Witness: That was when he was boozing. Prisoner had never swindled him before. Yes, he used to take about a picture as a specimen, and witness expected that picture to be returned—a picture he (witness) bought at a sale in Bridge Street. Mr. Lloyd: On the picture you put your own label over someone else's name?—Yes. Was it that of the "Forget-Me-Not" Portrait Painting Company?—Yes. Why didn't you send around your own picture?—I didn't have one of my own. Continuing, witness said he had sued people in the County Court, not because they refused the pictures, but because their payments were in arrears, and he denied that the County Court judges had ever made observations reflecting upon his pictures. Further examined, witness had never heard that the label was washed off by the rain, exposing the title of the "Forget-Me-Not" Company. When he discovered the fraud which you had perpetrated he said there was no wonder people made complaints?—Nothing of the kind. And then you decided to lock him up?—Not at all. Because he wouldn't close his mouth?—That's your suggestion, not his. Mr. Lloyd: Not a suggestion. It will be a fact presently. Witness denied allegations of making deductions from the man's wages, and said it was not a fact that he owed prisoner a balance of 3s. 10½d. In the course of a later sitting, the prosecutor stated that on February 24 prisoner came to his shop in the Wynd- ham Arcade and handed him five photographs (produced). On the backs were the names of the people who gave the orders for enlarge- ments, and by which the orders could be verified. Witness paid him 9s. commission on two of the photographs because prisoner said his wife was ill. He altogether gave prisoner 27s. 6d., of which 10s. was wages and 17s. 6d. commission, representing 3s. 6d. on each of five orders, two of which constituted the second charge against prisoner of obtaining 7s. from Stone. The evidence of a number of people was heard, to the effect that they had not paid deposits or given orders for enlargements. In further cross-examination of the prosecutor, Mr. Lloyd called for the production of books and wages sheets relating to transactions, but witness said there were no sheets, and he objected to bringing his books, and Kelsey was committed to the Quarter Sessions for trial and admitted to bail.

**ALLEGED POSTCARD FRAUDS.**—The further hearing of the case reported in our issue of February 16 last came before the Somerset Quarter Sessions last week. It will be remembered that Joshua William Humphreys, photographer, was indicted for obtaining by false pretences from Frederick Charles Durbin Hurd the sum of £2 7s. 6d. The case for the prosecution was that the accused, who had a studio at Blandford, took orders from the prosecutor, a sta- tioner, at Shepton Mallet, for the supply of picture postcards, who paid £2 7s. 6d. in advance, but no photos were sent, and he placed the matter in the hands of the police. Similar evidence was given by other witnesses. P.C. Pike said in ten weeks the accused had received orders for 50,000 postcards, and had received £113 15s. Mr. Wethered submitted there was no case to go to the jury, but the Chairman said it must proceed, though in his opinion it was not a

strong case. The accused was called and gave evidence as to his business transactions for the large supplies of P.O. printing on the cards with well-known London houses. He denied that he defrauded prosecutor. It was a real genuine business he was carrying on. In cross-examination the witness said he had had a number of orders for a thousand postcards. He had received the money, but he had not been able to execute the orders. He had received a sentence of four months for false pretences at Stroud in October last, where he pleaded guilty on the advice of the police. At the Wilts Quarter Sessions, on the advice of the Chairman that there was no bill, the indictment was withdrawn. The Chairman summed up strongly in favour of the accused, and told the jury they had to see that the criminal law was not pressed too hard. The jury returned a verdict of "Not guilty," and accused was discharged. In response to Mr. Wethered, the Chairman expressed the opinion that in regard to all the cases mentioned by the prosecution no further proceedings ought to be taken.

MR. ADOLPH LOWENSTEIN, 150, Mansion House Chambers, summoned in the City of London Court last week for the non-payment of £3 9s. due to a printer, was said to be the proprietor of the "Alliance Matrimonial Institute," of the "Smart Syndicate," the Santa Katalina Gold Mining Company, the American Photographic Enlargement Agency, the European Patents, and the Comfort Folding Patents. The defendant said he had nothing to do with any of the companies named, but Judge Lumley Smith said he believed the plaintiff, and the defendant would be committed for ten days, the order to be suspended while he paid £1 a month.

PREMIER Optical Company, Ltd.—Capital, £300, in £1 shares. Objects: To acquire the business of the Swift Optical Company, of 113, Romford Road, E., and to carry on the business of makers and dealers in optical goods, scientific instruments, cameras, lenses, and other photographic goods, etc. No initial public issue. Registered without articles of association. Registered office, 63, Bolton Road, Stratford, E.

PHOTOFILM, Ltd.—Capital, £2,500, in £1 shares. Objects: To carry on the business of manufacturers, importers, and exporters of, and dealers in, films, plates, paper, chemicals, and other materials for photographic purposes.

**LIBEL by Postcard.**—In the Chancery Division last week, before Mr. Justice Warrington, a motion in the case of "Monckton v. R. Dunn and Co." was heard. Mr. Whately appeared for Mrs. Monckton, a well-known actress, whose professional name is Miss Gertie Millar, and he asked for an injunction to restrain the defendants from publishing postcards on the back of which appeared a photograph of that lady, which the defendants represented was a true photograph of her. In one of these she was represented to have been photographed in a nightdress, and in others in different costumes which were not too abundant. As a matter of fact, she had never been taken in such costumes, and they amounted to a serious libel upon a married lady. His Lordship: A pictorial libel? Mr. Whately: Yes, of a gross character. He understood that the photographs complained of were produced in this way: The photograph of the head of Mrs. Monckton was attached to the body of another person who had been taken in the various costumes depicted. Mr. C. C. Scott, who appeared for the defendants, admitted that the photographs were produced as described, but he submitted that they were not libellous. Although the lady had not at present donned such garments, it was quite possible that in the course of her professional career she might have occasion to do so. In one of the photographs the plaintiff was depicted as emerging from the shell of an egg. Surely that was a very innocent suggestion. Now that the attention of the defendants, who had acted perfectly innocently, had been drawn to the matter they were willing to give an undertaking not to publish, etc., any of the photographs complained of until trial or further order. His Lordship, on that undertaking being given, said he would make no order on the motion.

**A LIVERPOOL Bankruptcy.**—At the Liverpool Bankruptcy Court on Friday, Mr. Rudd, on behalf of Thomas Edward Parkin, applied to the Court to vary an order made in February, 1902, suspending the discharge until 10s. in the £ was paid. The failure took place in 1899, when the applicant was in partnership with one Frederick George Fry, and they traded as Parkin and Fry, photographic mate-

rial manufacturers, in Etna Street, Old Swan, Liverpool. The discharge of Fredk. Fry had been refused. Mr. Rudd urged that the bankruptcy had been entirely brought about by the applicant's former partner, and that in the course of a partnership lasting only a few months the applicant had been "done" out of £1,300, all the money he possessed. His Honour granted the discharge, subject to six months' suspension.

**The Affairs of a German Court Photographer.**—Amongst the heaviest financial downfalls in the critical years 1901-2 was the ruin of the world-renowned photographic firm of W. Höffert, of Dresden. This firm had branches in many Germany towns, in Berlin, Hamburg, Cologne, Breslau, Hanover, Leipsic, Constance, etc. It had a splendid business, but as the result of reckless expenditure it got into financial difficulties, which finally resulted in a meeting of the creditors. Enormous amounts had to be paid for stock and usurious interest, and from the books no less than £40,000 was found to have been borrowed. The money was advanced by all classes; bankers, civil servants, small capitalists, veterinary surgeons, and even a clergyman were numbered amongst the creditors. The precarious condition of the latter was hidden for months. The proprietors apparently appeared as well-to-do merchants, and almost up to the financial downfall this world-wide firm was considered firmly established. Appearances, however, were deceptive. Numerous agents were at work to open up new sources of money. Twenty per cent. interest was willingly paid, and small capitalists were only too easily seduced by such a large interest to entrust their savings to the world-wide firm of Höffert. When the firm failed in April, 1902, no less than fifteen hundred creditors bewailed the loss of their money to the amount of several hundred thousand marks. The principal proprietor, W. Höffert, died shortly before the smash; his son, a reserve lieutenant, who managed the branch business in Breslau, Berlin, and Hanover, absconded, and the widow was left behind without means in Dresden. Meanwhile the State Attorney of Dresden had instituted an inquiry against the absconding son and his mother on account of fraud. In order to induce people to advance loans the firm had issued circulars offering high interest, and young Höffert appeared as a "reserve officer" with such world address, that people plainly considered it an honour to be permitted to lend money to the firm. In the summer of 1904, Höffert, junior, returned from Switzerland, where he had absconded, and he and his mother had to defend themselves against a charge of fraud before the Third Court of the Dresden Assizes. Höffert, junior, was sentenced to seven years, and his mother to five years, imprisonment, and both are now undergoing these sentences in the prison at Bautzen. The Supreme Court refused revision, and also a proposal for revival of the suit was thrown out. The widow Höffert now lies very ill in prison, and is hardly likely to leave it alive. Höffert junior has been brought up from the prison at Bautzen before the Dresden Assizes to answer for further frauds. He swindled, immediately before the bankruptcy of his firm, the lately deceased banker Oeser, out of £300, and his wife of £1,350, and a veterinary surgeon, Heerlich, of about £135; in these frauds his mother, who is so ill, participated. His sentence amounts in all to seven years and six months.

## News and Notes.

**ASTRONOMICAL Photography.**—The extent to which the camera enters into the work of the modern observatory is well exemplified in the report of the famous Harvard College Observatory for 1905. With the Draper 11in. and 8in. telescopes over 6,000 photographs were taken, including 1,133 of stellar spectra. The Bruce telescope contributed 523 plates (one resulting in the sensational discovery of Saturn's tenth satellite, and twenty-seven having exposures of four hours each), and the Arequipa branch observatory 2,200. From 1,580 determinations of the magnitude of the minor planet Eunoë a variability of half a magnitude in a period of 3 hrs. 24 min. was ascertained, and many interesting new variable stars were detected during the examinations of the plates of spectra.

**A REQUEST for Photographs.**—Mr. Francis Galton writes to "Nature" from 42, Rutland Gate, London, S.W.:—"I should be

ful to your photographic readers, whether amateur or professional, who would send me, within the next two or three weeks, the photographic portraits, to be cut up, mounted, reduced to a standard scale, and so to be published without names. They are used in considerable numbers to control results at which I have already arrived, relating to resemblance. Family portraits would be particularly acceptable. I make this appeal, finding it extremely desirable, as well as costly, to obtain the needed material in other ways."

**ACETYLENE-FEED Generators.**—It is necessary to notice that the expression "carbide-feed" generators is no longer sufficiently precise to describe those types of carbide-to-water apparatus in which carbide is fed into the water of decomposition by automatic mechanism. In their original forms (says "Acetylene") the introduction of the carbide into the water in these generators was effected about by gravitation or some similar force, the descent of the holder bell to a certain pre-determined position causing a valve to open, unlocking the movable bottom of some receptacle, driving some forwarding gear through the action of a ratchet pawl. Now, however, builders are constructing carbide-to-water generators of the automatic kind in which the feed of the carbide is effected positively by means of some mechanism foreign to the apparatus itself, i.e., by means of a train of wheels actuated by spring or falling weight. In this type, we gather, the descent of the holder bell has nothing to do but to release the mechanism in question, so that the work suddenly thrown on the bell is too little to absorb much of the gas pressure. It has always appeared an objectionable feature in an acetylene generator fitted with a ratchet holder that the bell should suddenly be called upon to do more work other than that of forcing the gas through the service, because the additional work is at all heavy the pressure at the burners is diminished as long as the bell is otherwise engaged, and thus illuminating power and general behaviour of the burners must temporarily suffer. Naturally, if the additional duty thrown on the bell is quite small as compared with what it has to do in forcing the burners, and if the said additional work lasts only for a moment (as in opening a water valve), there is no harm done and causing an instantaneous jump in the light, but even this is not to be welcomed.

### A MAGNIFICENT OFFER.

To the Editors.

Gentlemen,—You speak pretty often in the B.J.P. about cheap work among photographers and their helps in England. I cannot stop showing you what can be done on the Continent in that line, I do not think it can be easily beaten. I read in a newspaper following advertisement, which I enclose in this letter:—

"Operators, possessing an outfit of 5in. by 7in. sized plates wanted, to travel.—Address, etc."

A matter of curiosity I went to the advertiser, thinking that there must be something behind it. I was well received, and upon my inquiry as to what the work was to be and the salary, I was informed that I was to take photographs while travelling in the West of France, and take views of shops or stores, that I was to pay all travelling expenses, hotels, and dry plates. These plates, which were to be furnished to me and paid by me to the employer, would cost 2s. a dozen (exactly 2 francs 40 centimes). The views, when taken, would be developed by employer, and expected to be good. When I asked what I would be paid for each negative forwarded supposed good, I was informed that I would receive 0.40 centimes each one, or 4d., and, mind you, the plates cost me already 2d. On my astonishment at such low figures I was told that I could

easily earn at that rate the munificent sum of 8s. a day, which means my taking fifty negatives each day, and I had to canvass for finding these fifty customers each day, take the views, and no account was made for a rainy day or days as are common in Normandy. Supposing I would be able to earn these 8s., I was to take out of these my travelling expenses, hotel bills, furnish my own instruments, dress, and if I have a family, let them starve. I forgot also of much use, but it is interesting, only he did not inquire about, and therefore will not put these in line.—Yours very truly,

RENVERSANT.

### MEASURING SHUTTER SPEEDS.

To the Editors.

Gentlemen,—Mr. Watkins is rather unlucky with his formula. I do not know whether the relation he has found between the "swing," the periodic time, and the velocity at lowest point is of much use, but it is interesting, only he has not stated it correctly.

For small arcs the velocity at lowest point is  $\theta \sqrt{g/r}$  ( $r$  = radius of circle and  $\theta$  = angle at centre subtended by half swing). The

swing is  $2r\theta$ , and the time is  $\pi \sqrt{\frac{r}{g}}$

Hence  $\frac{\text{swing}}{\text{time}} = \frac{2}{\pi} \times \theta \sqrt{g/r} = \frac{2}{\pi} V$ , and taking the usual ap-

proximate value  $\pi = \frac{22}{7}$ , we have  $\frac{\text{swing}}{\text{time}} = \frac{7}{11} V$ ,

or  $\frac{11 \times \text{swing}}{\text{time}} = 7V$ , not  $= V$

C. E. F. N.

To the Editors.

Gentlemen,—I have read with some interest the letters from Mr. Watkins on his method of testing shutter speeds. A simple plan, such as the one described, that will give results with approximate accuracy, is much to be desired, and as Mr. Watkins gives the benefit of his invention to all who wish to avail themselves of it, your criticism need not be wholly destructive. Though a nail suspension sounds crude I do not take it to be an essential feature of the apparatus, or to preclude the use of a knife edge or other more delicate form of pivot.

If your formula  $\frac{s-m}{2\theta\sqrt{2L}}$  is worth anything, it should be

accurate over such a small angle as would be described in the 1-50th of a second, say,  $1\frac{1}{2}$  deg. Will you be good enough to give the working on which your formula rests, or to work out the example of which Mr. Watkins gives the data, your readers will then be better able to judge of its utility.

I have recently had my shutter speeds tested by a well-known lens maker, and I see that they state on the test sheet that "the speeds given are practically, though not scientifically, accurate." Probably Mr. Watkins would say the same of his.

Mr. Carnegie may have a better method of testing shutters "of which the underlying principles are dynamically sound," but of that he is the sole judge, and your readers do not benefit thereby until he lays it before them.—I am, dear Sirs, yours faithfully,

C. J. BOSANQUET.

Blackheath, April 3.

[We have an article appearing shortly on the movement of a pendulum, and will postpone further reference to the present controversy until its publication.—Eds. B.J.P.]

### THREE-COLOUR PORTRAITURE.

To the Editors.

Gentlemen,—With reference to the correspondence by your contributor in this week's issue, we would like to state for the edification of Mr. S. Elwin Neame and others, that it is quite easily possible to obtain exposures in the studio with Dr. Koenig's three rapid filters in from 4-5 seconds for the three exposures, so that the drawbacks mentioned by your contributor must only be put down to a want of information on his part.—Yours truly,

FUERST BROS.

17, Philpot Lane, London, E.C.

April 6, 1906.

## Answers to Correspondents.

- \* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- R. H. Midwinter, 43, Park Street, Bristol. *Photograph of Miss Nellie Carter.*
- E. Wilkinson, The Studio, Hornsea, Yorkshire. *Three Photographs Showing Hornsea Promenade in a Storm.*
- F. V. A. Lloyd, 15, Lord Street, Liverpool. *Two Photographs:—Two Dark and One White Drum Horses and Riders, styled Ladysmith Horses, 18th Hussars. One White Drum Horse and Rider, styled White Willie, 18th Hussars.*
- A. Addington, 23, Lincoln Street, Kingsthorpe, Northampton. *Photograph (Combination) of Nine Different Views of Kingsthorpe.*
- T. M. Paul, 35, Marsh Street, Middlesbrough. *Photograph (Combination) of Mille. Von-Elia.*
- W. Laws, 154, South Eldon Street, South Shields. *Three Photographs of the Official Inauguration of the South Shields Electric Trams.*
- G. A. Dean, 14, High Street, Rugby. *Photograph of the Interior of Men's Ward (The Benn) Hospital of St. Cross, Rugby. Photograph of the Interior of Women's Ward (The Elizabeth), same Hospital.*
- T. K. Frank, 15, The Crescent, Gateshead. *Photograph of "S.S. Greytote Castle."*
- E. E. Corke, 82, High Street, Sidcup. *Two Photographs of the Rev. B. W. Chancellor, M.A.*
- E. Crowe, Thorofare, Harleston, Norfolk. *Photograph of the Screen in the Parish Church at Eye, Suffolk. Photograph of the Interior of Eye Parish Church.*
- C. Smy, 75, High Street, Upper Houghton, Dunstable. *Photograph of the Interior of the Parish Church at Houghton Regis, Dunstable.*
- A. Shaw, 32, Briardale Road, Seacombe, Cheshire. *Photograph of the "S.S. Fearless" with Back Broken, Eyremont.*

OPALINES.—1. I have to mount local prints in contact with glass and affix the glass to push frames for a customer, using P.O.P. (a gelatine paper). I thought it would be sufficient if I squeegeed them on to the warm glass, but they come off in places. I also used glue to affix to the push, but this has faded the prints wherever it has touched in a week or two. Will you kindly tell me the best way to do; it is for sea-side (cut) trade, and so I do not want more expensive proceedings than I can help. I think these are called opalines. 2. In a note to a letter on p. 279 of this week's issue you say: "Excellent cold varnishes can be obtained commercially which can be applied in a minute or two with a brush." Could you give the names of some reliable cold varnishes, as my place of business is at some distance from residence, and I have such a difficulty in hot varnishing, but have never used cold, as I thought they were not good enough to use?—WEDE.

1. If you are using gelatine prints and no alum bath you should have no difficulty in getting the prints to hold. However, a weak tepid solution of gelatine in which they are soaked for five minutes before squeegeeing will cause them to adhere. Glue is not a safe mountant. Use a gelatine mountant, such as the following from the "Almanac":—

Nelson's No. 1 gelatine ..... 4 oz.  
Water ..... 16 oz.

Soften the gelatine in water, liquify by placing the vessel in hot water, and add, a little at a time, and stirring rapidly,  
Methylated spirit ..... 5 oz.  
Glycerine ..... 1 oz.

2. If you state your requirements to any of the large dealers, such as Fallowfield or Marion, they can supply you with a cold varnish.

A. H. MOWERAY.—1 and 2. We regret that we have not directly compared the lenses; it is therefore impossible for us to answer these. 3. Depth of focus is a function of the aperture and focal length.

ANXIOUS, CLAPHAM.—Probably the instrument you want is the neocyclostyle; the address is 83, Gracechurch Street, E.C.

NIGHT PHOTOGRAPHY.—1. Will you tell me if I can get anything of a photograph of a florist's shop at night time with the lights? If so, how shall I have to go about it, for if I can take it they will give me a good order, but I do not want to use any flashlight. 2. Will you please tell me what kind of a coil I shall want to explode some flashlight powder (it is called Bayer flash powder). It does not go off so very well with a light, but if you drop a red-hot cinder into it or touch it with the red-hot poker it will go off very well. I thought of a coil that would make a piece of platinum wire than was in a coil in the heap of powder red-hot. —THOS. DELICATE.

1. If you work at dusk when there is enough light to illuminate details in the scene, you will have no difficulty in getting a very satisfactory photograph with an exposure of a minute or two at a fairly large aperture, such as  $f/6$  or  $f/8$ . You should, of course, use a backed plate. 2. A couple of bichromate cells should answer your purpose. A dealer in electrical goods will supply you.

FOCUS OF LENS.—Can you kindly oblige me with a couple of methods of determining the focus of a single bi-concave (negative) lens?—T. C. S.

The lens is placed in contact with a positive lens of sufficient (known) focal length to give a resultant positive focal length. This latter is measured by any of the usual methods, and the focal length of the negative calculated from the formula  $F = \frac{f_1 \cdot f_2}{f_1 + f_2}$ . Where F is the focal length of combination,  $f_1$   $f_2$  of those of the separate lenses.

STUDIO QUERIES.—Will you kindly answer me the following questions? No. 1. Is it possible to do good all-round work in studio 22ft. x 12ft.? No. 2. The studio would have to face direct east, therefore what would be the best thing to glaze it with? How much solid each end, etc.? No. 3. My present studio is built of corrugated iron, lined with matchboards. It gets so hot in the summer and cold in winter that it makes it unpleasant for sitters. How can I build another to keep a more even temperature. No. 4. How high should the eaves be and height to ridge? I should be so very much obliged as a reader for several years of B.J.P. for any useful information.—X. Y. Z.

1. Yes, certainly. But the studio would be better if it could be made three or four feet longer, particularly for groups. 2. The roof might be either white rolled plate or clear glass. The side plain or fluted glass. The latter would be the preferable if the studio is overlooked by close neighbours. About four feet six or five feet for a studio of these dimensions. 3. If one or two thickness of roofing felt, which is a good non-conductor of heat, intervenes between the matchboarding and the iron, the temperature will be kept more even. Two or three inches of saw dust between them will serve the same purpose. 4. About twelve feet to the ridge and eight feet to the eaves will be about right.

\*\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

exhibition of portraiture by R. Dührkoop, at the offices of BRITISH JOURNAL OF PHOTOGRAPHY will be opened also on sday evenings from 6 to 8.

methods to be followed in making a combination negative are d in an editorial. (P. 303.)

ography, by the inclusion of the Manchester Municipal al School, in the Victoria University, becomes one of the nents of the Faculty of Technology, and is to be selected of the optional subjects for the B.Sc. (Vict.) degree. (P. 302.)

G. F. M. Hopkins, in a paper before the Oxford Camera discussed certain aims and methods in portrait photography. (P. 304.)

ording to an Austrian worker, Herr Heicke, enlargements by al light may be made direct on gum-bichromate paper by the sensitive surface a supplementary even exposure to light. (P. 305.)

cent copyright decision in the High Courts has affirmed that ncession of certain rights to sell copies of a photograph is ble consideration," and that therefore the copyright of photo- taken under such circumstances is the property of the person the concession. (P. 319.)

invention of self-toning paper in 1888 is claimed by D. ch, writing from Baltimore, U.S.A. (P. 319.)

exposing chamber for plates or films, and improvements in is and shutters are among the patents of the week. (P. 313.)

first of a series of articles by E. J. Wall, F.R.P.S., dealing the use of the spectroscope treats of the construction of the he spectroscope. (P. 307.)

on tetrachloride is recommended by Valenta as a solvent for n-making purposes. (P. 310.)

John Bartlett advises photographers aiming at art photography field of figure work to eschew personal friends and actors ers, and select only the professional model. (P. 311.)

## EX CATHEDRA.

### An Important Copyright Case.

The letter from Mr. Stackemann in another column this week draws attention to a copyright case, in which he was the plaintiff, which seems of the very greatest importance to the profession. The case, *Stackemann v. Paton*, has not yet been reported in the Press, but as soon as the Easter recess is over a verbatim report will be available. The importance of the action, however, lies in the ruling of Justice Farwell that certain limited concessions to a photographer in the way of issuing copies of a photograph is a good and valuable consideration, and therefore the copyright in the photograph becomes the property of the party making the concession. This, according to the information of Mr. Stackemann, was the ground upon which the case was decided, and those who have studied the copyright cases of the past will see that it reverses previous decisions of the courts. As communicated to us *viva voce*, the case was briefly as follows:—The plaintiff, trading as the Photographic Tourists' Association, was in the habit of photographing the exterior and interior of schools, taking the photographs at his own risk, and the proprietors of the schools ordering copies if they approved of them. Several of the photographs made under these circumstances having been published in a book issued by the defendant, the action was brought for infringement of the plaintiff's copyright, but was lost on the ground we have already mentioned. It will be better, perhaps, for us to postpone further reference to the case until the verbatim report is available, but if the facts as we state them are correct, the ruling must be highly prejudicial to photographers' interests, and must introduce the very greatest uncertainty into the so-called "free-sitting" business.

\* \* \*

### Orthochromatism.

We seem to be in for a season of strenuous orthochromatism, or shall we not say panchromatism. We believe that recent accessions to the list of colour-sensitive dry plates has destroyed the small minority of makers who did not issue an orthochromatic plate. As our columns have shown during the past few weeks, plate makers are alive to the need of a suitable screen for their colour plates, and themselves are taking steps to see that the user gets it. The issue of bathed plates has further concentrated interest on orthochromatic methods, and now we have the offer of a firm to orthochromatise plates to order. The user may make his choice among the pinachromes and cyanols, and obtain his pet sensitiveness without the *embarras* of home sensitising and drying. It remains to be seen what use will be made of these new processes in portrait photography. Probably retouchers still feel secure in the natural conservatism of photographers.

### Figures in Landscapes.

When visiting exhibitions one cannot help being struck with the value a figure or figures are in a landscape picture, and also, in many instances, how many pictures would be improved if a suitable figure had been introduced at the right point. Most are aware of the desirability of the figures at the time the pictures are taken, but the difficulty of obtaining a suitable one is frequently unsurmountable. Many, however, do not seem to realise how simple a matter it is to introduce a figure or group of figures into a landscape, or, say, a horse and cart into a picture of a country lane, in the printing of the picture. Of course, it has to be done by double printing, but this is a very easy matter if the simplest method of working be adopted. In our issue of March 2 (see p. 162) appeared an article on combination printing, and one of the methods there described is applicable to the introduction of figures, or anything else, into landscapes. Suppose, for example, it is desired to introduce a figure or two into a landscape, or, maybe, a vehicle of some sort into a photograph of a road or lane. We must first obtain a small negative of the figures, and it goes without saying that they must be of suitable size, and the lighting must correspond with that of the picture in which they are to be introduced. The background and everything else not desired is then neatly blocked out with black varnish, and this negative is then printed to the right depth to suit the picture on a piece of paper the size of the landscape negative, the portions beyond the small negative being shielded from light while printing. We thus have the figure on white paper. It is then neatly painted over with gamboge. The landscape is then printed, the paper being put on the negative, so that the figure appears in the place intended and the landscape printed. The picture is then toned and fixed in the ordinary way, whilst the free silver is washed out of the paper prior to toning, the gamboge is also washed off, and leaves no stain behind—that is, if albumen or collodion-chloride paper be employed. This is not the case with all samples of gelatine papers, as with some a stain is left; with others, however, there may be none.

### Colour Photography in Glasgow.

A large proportion of the specimens of colour photography which were exhibited at these offices in January and February have been brought together in the studio of Mr. Lewis P. Muirhead, of Glasgow, where they will remain open to inspection by the public for a week or two. One or two of the exhibits represent advances in practice even within the short time which has elapsed since the closing of the exhibition at our offices. Among these is a three-colour print by a modified pinatype process shown by M. Vidal, who has communicated to us a description of the process for appearance in our columns at an early date. We congratulate Mr. Muirhead upon his enterprise in showing Scotsmen the latest achievements in trichromatic methods, and we hope that the exhibition will stimulate interest in the processes among Scottish workers. At the conclusion of the Glasgow exhibition steps will be taken by the Royal Photographic Society to house a representative selection of the exhibits, originally brought together by ourselves, in their premises at Russell Square.

### A Professorial Chair of Photography.

Those who have laboured to elevate and advance the science of photography will be glad to hear that by the entrance of the Manchester Municipal Technical School into the Victoria University as the Faculty of Technology, photography and its cognate branches takes their place among the other departments of applied science recognised in

the University's wide educational scheme. The occupation of the first professorial chair of photography thus falls to Charles W. Gamble, by whom the department of photographic and photo-mechanical techniques at Manchester was organised and arranged with the experience gained as Principal of the London County Council School of Photo-Engraving and Lithography, Bolt Court, in the leading Continental schools. Under the arrangements photography is one of the optional subjects for candidates for the B.Sc. degree in applied chemistry and the Victoria University may thus be looked upon as the first training ground for scientific photographers and photo-chemists. The new prospectus of the University curriculum shows the precise part which photography occupies, and should be studied by those desirous of taking a science degree with photography as one of the subjects. We are glad to see that no relaxation of the necessary training in mathematics and pure physics and chemistry is proposed for students of this and other branches of chemical technology.

\* \* \*

### The Dührkoop Exhibition.

In continuation of our note of last week offering to open the collection of portraits and portrait studies now being exhibited at our offices on one evening in the week, we have to announce to the numerous correspondents who have written thanking us and approving of the suggestion that the exhibition may be seen on Wednesday evening from 6 to 8. Some brief notices of the work of H. Dührkoop by the daily press appear on another page. A review will appear in our own pages next week. Meanwhile we have only to say that all readers and friends of THE BRITISH JOURNAL OF PHOTOGRAPHY are invited to pay a visit to 24, Wellington Street. The occasion, it is hoped, will be one on which they will discover something to interest them if not a good deal which they can study with profit.

\* \* \*

### The Free Portrait Dodge in Germany.

What is a variant of the free portrait dodge has cropped up in Berlin. A circular was left at each house, and the top was a puzzle, which we reprint:—

Edej  
Eilimaf  
Tähre  
Nie  
Dnalar  
Tiartrop.

Anyone who solved this, and each line forms a word at the whole a sentence, as will be obvious to those of our readers who know German, had merely to send sixpence to a certain art institute, and they would receive a 18 by 14 inch enlargement. The secret of the above puzzle is that the German words are simply reversed, and the actual reading is "jede Familie erhält ein Roland portrait", or, in English, "every family may obtain a Roland portrait." Of course, when the portrait was made it was essential to purchase a frame. On the same circular particular attention was called to the "oil portraits" at 15 shillings, the pastels at 12 shillings, and black pastels at 10 shillings.

\* \* \*

### Portraits taken in the studio with natural backgrounds.

Many photographers may be presumed to be looking out just now for novelty in the way of portraiture for the coming season. Those in pleasure resorts might induce many visitors to have their portraits taken with a background depicting some of the well-known scenery or places of interest in the neighbourhood.

Some portraitists do have backgrounds painted to represent them, but their number is limited, and, after they show only as painted backgrounds. There is no reason, however, why natural backgrounds themselves should not be employed, and the above paragraph calls to mind a method introduced many years ago by Mr. Edge, of Llandudno, which he worked commercially, and with which he produced thousands of pictures, finding the process highly remunerative. Although the method is, as is said, old, it will be novel to many at the present time and may be of use to some. A series of stock negatives are secured of the scenes desired. They should be taken at such a distance that a figure posed in the foreground would be, say, of the cabinet size—that is, for cabinet portraits—and show the amount of subject desired on the background. These are the stock backgrounds, and they serve for any number of different portraits. The portraits are taken in the studio in the ordinary way before a light grey background. The portrait negative is then made, and, of course, has only a very light-tinted background. The figure is then painted over with gamboge, as directed above. This, in Mr. Edge's establishment, was done by girls. The landscape background is then printed, the printing being kept light. The prints are then washed, dried, and fixed in the ordinary way. In washing out the nitrate of silver from the paper the gamboge comes away, so that it causes no trouble whatever. The reason for using a light-grey background instead of a white one in the studio portrait is that a tint is obtained, which, when the background is printed, gives atmosphere to it. Any of our older readers will remember Mr. Edge's work on the very artistic pictures he produced. There seems no doubt, in our mind, that if enterprising portraitists at pleasure resorts were to make a feature of this simple method of producing portraits with natural backgrounds, Mr. Edge's method they could obtain much enhanced pleasure for them. The same portrait might be printed with several different backgrounds, and, when that were desired, a still higher price could be charged. A dozen portraits could be produced each with a different background, and depicting a different scene, with no more trouble than making the same for all.

#### COMBINING SEVERAL NEGATIVES INTO ONE.

In the conclusion of the article on "Combination Printing" in the issue for the 2nd ult. (see page 163) it was mentioned that when a considerable number of prints of the same subject are required it is best to make a combined negative rather than to repeat the combination for each individual print of the two negatives. It goes without saying that when once the combined negative is obtained the printing involves no more trouble than that of any other, and, furthermore, the prints will be more generally uniform than when made by the double combination. In the article just referred to it was assumed, as a way of illustration, that one or more figures which were not present when a group was taken had to be introduced into the picture. It will now be assumed that the same object is in view, and that instead of only four or five prints being required as many dozens have to be produced. In this case it is far less trouble in the end to make a combined negative, and thus be able to obtain many prints at a single printing. There are different methods of making combination negatives, but, whichever is selected, if it be known when the group negative is taken that other figures have to be included provision could be made for them in posing the group. We will now describe one method that may be employed, and we

shall assume, as in the previous article, that the original group is of the 12 by 10 size, though, of course, what is to be said applies equally to negatives of any dimensions. The film of the negative of the portrait to be introduced is first stripped from the glass by any of the well-known methods, or the portrait may be taken on a thin celluloid film. The film negative, whichever it may be, is then placed in the desired position on the large negative and the figure cut round with a sharp penknife, using sufficient force to cut through to the glass. The film of the large negative is then neatly scraped away and the new one introduced in its place, and secured there with a few touches of gum. In this way the original negatives are used, but in order to obtain a successful result it is imperative that the printing value of the second negative be identical with that of the first, otherwise the result will not be at all satisfactory.

By far the best way of proceeding is to reproduce the negatives through the medium of transparencies, making the actual combination in them. This plan, it is true, involves a little more trouble than that just described, but such is amply repaid in the superior excellence of the results obtainable. In this method of procedure the transparencies must be in film form. They may be printed on dry plates, and the films afterwards stripped off; or they may be made on the thin rollable celluloid films. But with either of these methods there may be some little difficulty, at times, in getting them all of exactly the same printing value, and, moreover, in the case of celluloid, it is a little difficult to cut through cleanly. For these reasons it is best to make the transparencies by the carbon process, using the ordinary transparency tissue for the purpose. With carbon the question of colour does not come in, as all will be the same, so that the printing density is readily judged of and made equal in the development; all the transparencies can thus be obtained with the greatest uniformity. It may be mentioned here that the transparencies should be much more deeply printed than if they were for lantern slides; indeed, as deeply as if they were to be used for enlarging from—there should be absolutely no bare glass anywhere, except, perhaps, in the very highest lights.

The transparencies must be developed on collodionised plain glass as described in the double transfer carbon process (see *Printing Processes*, XX., page 264 ante). Perfect transparencies of the requisite density having been obtained, they are flowed over, while still wet, once or twice with a warm dilute solution of gelatine (say one ounce of Nelson's No. 1 in a pint of water), and allowed to dry. They are then coated with enamel collodion and again allowed to dry. When thoroughly dry, and not before, the films are cut round the edges and stripped from the glass, which they will leave readily. We now have the transparencies ready for combining. The reason for coating them with gelatine, it may be mentioned, is to prevent the second coating of collodion from dissolving the first—that on the glass—in the highest lights.

The combination is made as follows:—The largest transparency—that made from the large negative—is firmly secured to a glass plate—preferably a little larger than itself—round the edges with strips of gum paper. The plate is then put on the retouching desk and one of the small film transparencies bearing the figure to be introduced is adjusted in its place and temporarily secured in position at the edges with a few touches of indiarubber solution—such as is used for repairing cycle tyres. This being done, the figure is neatly cut round with a sharp, thin penknife, used with sufficient pressure to cut clean through both films at once. The uppermost film is then removed, the rubber cement allowing of that being done,

the cut-out piece of the under one taken away and the other one put into its place where it will fit accurately. It is then cemented in position with a few touches of gum applied to the figure portion—not the face. Any other portraits that have to be introduced are dealt with in the same manner. In this way we get a combination transparency which, if the work has been neatly done, will show no joins, and will have all portions of equal printing value. From this combined transparency a negative, or several negatives, may be produced. They may be made by contact printing on dry plates, or by the carbon process. Or they may be produced in the camera in any desired

size. By making the combination with the transparencies the original negatives remain intact.

It will be seen from the above that it is quite an easy matter to build up excellent combination groups of persons, although the negatives of the individuals composing it were all taken at different times. In the foregoing only portraiture is dealt with, but it will be obvious to everyone that the system is also applicable to landscapes. For example, in taking a picture the size of the plate may not include the whole of the subject desired. But if two negatives are taken at the time they can be afterwards combined by the method just described

## PORTRAITURE.

A Paper read before the Oxford Camera Club last week.

In a recent lecture on Art the statement was made that "Raphael's best pictures were those he never painted." What the lecturer exactly intended to convey in this paradoxical saying I am not sure; but how true it is in one sense all art workers are sadly aware. Our best productions are always those we have only seen in our waking dreams, in what we call "our mind's eye"; those perfectly satisfactory achievements which seem so possible till we attempt to translate them into fact!

### Portrait and Likeness.

The perfect portrait is so rare that it may almost be called non-existent, and the attempt to produce it in photography gives rise to more disappointment than perhaps any other branch of the art. The reasons for this are numerous. I suppose we are all pretty well agreed about what constitutes a good portrait. If asked for a definition, most people would give this: A faithful and pleasing likeness; or possibly, a faithful *but* pleasing likeness. And in the "but" lies all the difficulty! I suppose, judging by what we see in exhibitions, both of painting and photography, that there does exist a certain number of people who prefer *unpleasing* presentments of themselves or their friends; at any rate, the artists' tastes seem to run in this direction. This is no doubt partly due to the modern craze for "actuality," as it is called, and to the excessive emphasising of one particular phase of the sitter's personality, to the exclusion of all the other thousand traits which go to make up the human character. This doubtful fashion in art, however, like other fashions, will have its day and subside into obscurity. If, however, any photographer wishes to follow it, he will not find it very difficult up to a certain point. He will probably not be able to emulate certain eminent painters, who contrive to put into some of their sitters' faces traits of character which, whether they exist or not, might almost furnish material for a libel action. Such triumphs are reserved for the more plastic arts. Photography must be content with representing things as they are—only let us be careful to represent them as they really are, as far as we can, for our limitations are somewhat severe.

First of all, let us get a clear idea of what our sitter really is like, and what impression we must endeavour to convey to the world of this particular human being. A true appreciation is seldom obtained by one interview; if possible we should see our sitter several times in the case of a stranger to us; with acquaintances and friends the task is easier. The several somewhat varying impressions thus received must be compared, and a general composite one obtained. If this is felt to be unsatisfactory, some one of the *pleasantly* characteristic impressions should be selected, mental notes being taken of details of lighting, costume, etc.

### Orthochromatic Portraiture.

Having determined what we wish our portrait to look like, we must consider our means. It will be found, in thinking over the characteristic points of anyone's personal appearance, that colour plays a very important part. And the rendering of colour is one of our chief stumbling-blocks. The difficulties connected with it are twofold, viz., those belonging to any rendering of colour by monochrome, and those peculiar to photography. Careful study of tone-values, and practice in trying to render them correctly, help to overcome the first, but technical knowledge in addition must be employed to grapple with the second. For example, in photographing a person with blue eyes, pink and white complexion, and auburn hair, we have not only to find out the relative depth of tone of the various colours, but also to reckon with the fact that blue will appear nearly white, and pink and auburn approaching black, in a photographic print, unless we take means to remedy this misrepresentation. Colour-sensitive (orthochromatic) plates, with or without coloured screen, should often be used, especially where defects such as freckles exist, but care must be taken not to overdo the use of these devices, or we may get the opposite result to that aimed at, e.g., blue eyes may look black and auburn hair nearly white. Care in development helps much towards correct colour rendering; parts of the negative which threaten to become too dense can be stopped, while others are coaxied into density. It will be seen that in order to do this with success a clear idea of the colour result desired must be kept in mind, and here comes in the use of the study of tone-values, or relative depths of various colours.

Printing, too, plays an important part in colour-rendering. Printing processes suitable to the negative and subject should be chosen. The best processes for portraits are certainly carbon and platinum, as both render the delicate gradation of tone required far better than other processes; unless, indeed, it is required to suppress detail, or obtain a broad effect, when bromide or gum-bichromate prints are most satisfactory. P.O.P. and albumenised silver paper come between, and are not really so effective as either, except in a few cases. A fairly good carbon-like effect is obtained by drying P.O.P. in contact with matt-surfaced celluloid, a good deal more detail and a pleasing surface are thus obtained.

### The Real Rembrandt Lighting.

All said and done, however, the absence of real colour from a presentment of the human face must remain a great disadvantage, and we can only partially atone for it by judicious lighting and posing. In studying the question of lighting, we can, as everyone knows, get much help from observation of

works of great artists, especially such as Rembrandt and others. These masters are particularly useful, in so much as their model are generally homely, if not ugly, whereas others like Vandyck, and even Reynolds, have a knack of trying to have had only handsome sitters, who would look in any light. The poses of the last-named artists (and schools) are frequently too artificial, though charming, of much use as guides to us, and the models seem to all possessed hands of the same beautiful and useless type. Hands of the Flemish and Dutch schools are, on the contrary, lifelike and natural in their various types and positions. If the lighting of a number of Rembrandt portraits studied, it will be found that the portion of the face and in bright light is almost always in the form of an oblong shape, with a piece taken out of it—never, I think, a egg shape, as is often seen in photographic portraits lighted from the side. This particular lighting is not very easy to obtain in an ordinary room, though in a studio it is easy to do it. Some light must be thrown from above or underneath in addition to that coming from the window. Of course, lighting must be adapted to the type of face being operated on, nothing but practice can teach how this is to be done. Rembrandt was very clever in the lighting of eyes; and it is good practice to try to copy some of his effects. Often quite magnificent eyes can be made interesting by throwing them in shadow, which must, of course, be transparent shadow. The transparency of shadow is much helped by the use of chromatic plates and care in development. A source of trouble in connection with the eyes is their surface polish, which, transparent and limpid in nature, often gives a glassy, unnaturally glaring effect in a photograph. This must be taken into account in arranging the lighting, as it often escapes notice when revealed in the print. Eyes are generally most pleasingly presented when looking naturally in front, not turned at an opposite angle to the face, or looking much away from the lens, though sometimes the face may be turned away and the eyes directed to the lens with advantage. Bunches of hair do not light up well, and should be avoided. They

usually resemble black and white rags more than anything else. Flowers, which form such beautiful studies, resent being treated as accessories, and demand special lighting.

### Back-ground and Accessories.

Accessories may help or hinder a picture. When thoroughly appropriate they are very desirable, but they seldom are unless the sitter can be pictured in his own room among his ordinary surroundings. A portrait of an artist or student becomes doubly interesting when taken in the midst of his paints or books, but such things introduced into a studio portrait look absurd and pretentious. Taste, however, no longer runs in this direction, as in the days when Lewis Carroll wrote "Hiawatha's Photographs."

The use of black backgrounds is condemned by many good critics, and I think that dead black screens are certainly to be avoided. If we examine Rembrandt's or Velasquez's dark backgrounds we shall find them always of a luminous quality, even if not shaded into half-light, as they frequently are. Against a dead black, the face is apt to look as if cut out of cardboard, without roundness. This failing may be observed in some very fashionable photographer's portraits.

The arrangement of the principal object on the plate belongs properly to the subject of composition, about which the Oxford Club has had much valuable advice from Mr. Snowden Ward and others, so I will only say that great care should be given to this point, if a good picture is to be produced. We do not always know why a picture pleases us, and very often it will be found on consideration that the arrangement of the chief masses according to rules of composition has a great deal to do with the matter. One chief rule is that the chief object should not be placed in the centre of the plate, especially when it is a seated figure and when accessories are included. I have indicated a few "side lights" which will, I hope, if not new or particularly useful, at any rate not help to darken the path of the aspiring portraitist as he struggles towards the full light of successful achievement.

G. F. M. HOPKINS.

## DIRECT ENLARGEMENTS IN MONOCHROME AND THREE-COLOUR IN GUM BICHROMATE.

The following article by Dr. Richard Hiecke, of Vienna, which appears in the current issue of the "Photographische Korrespondenz," should interest those of our readers who are workers in gum-bichromate, and whilst the author refers especially to three-colour prints, it is obvious that it may also be used for monochrome pictures. It seems an obvious sequence, too, that by adopting this plan it would be possible to obtain enlargements direct on ordinary carbon tissue.—Eds. B.J.P.]

In making enlarged gum prints it is usual to make a transparency to contact from the small negative, and then to make an enlarged negative. Even for a monochrome gum print it is necessary to develop three plates; with a three-colour print, however, at least nine are required. The result is considerable complication, as well as plentiful opportunities for failures and other inconveniences.

A process of making enlargements direct which would avoid the above roundabout methods appears, therefore, very desirable, even if longer exposures had actually to be given. The experiments which were instituted in following out this plan proved that the times of exposure with suitable arrangements were not so inordinately long; that actually from fifteen to twenty minutes was quite enough, and that even six minutes was sufficient for individual prints.

The enlarged image was projected by an ordinary lantern lens with an arc lamp of twelve ampères. An ordinary double

condenser of 4 in. diameter was used, with a Steinheil anti-planet of 1 in. aperture without a stop.\*

The three negatives of the tricolour set which were used for the experiment were clean and almost hard; the size of the enlargement was 2.8 times linear. The paper used was Schöller-Hammer paper sized with chrome-alum-gelatine, according to Kosel's formula. The pigment mixture consisted of one-part of gum solution (60 parts of gum arabic in 100 of water) and two parts of a 10 per cent. solution of potassium bichromate, with the requisite quantities of tube colours.

The exposure required for each of the three colours was about twenty minutes. The prints gave, however, as was only to be expected in gum-bichromate, only a few of the lightest gradations of the negative, so that to obtain a perfect three-colour print, at least six exposures, each of twenty minutes, or two

\* Although the author does not give the focus and aperture of the lens, the only one that we can find corresponding to this aperture is the group-aplanat of 7 in. focus, which worked at about  $f/5$ .—Eds. B.J.P.

hours' exposure in all, were required. It became necessary, therefore, to try and obtain a reduction of the exposure. Here I happened on a process which not only solved this question, but also had the further advantage that it reduced the number of printings to one for each colour.

#### Supplementary Illumination to Reduce Exposure.

The process consists of illuminating during exposure the sensitive paper on which the negative is projected by a supplementary light of even strength over the whole of the surface. The action of this supplementary lighting ought naturally not go so far that the high-lights remain coloured during development; the limits here laid down, however, are fairly wide in consequence of the variation in the duration and forcing of the development. By this supplemental lighting the exposure on the one hand is considerably reduced, and on the other hand the number of gradations of the negative projected can be increased at will, so that the softness of the prints is under control.

This appears at first sight almost too much to be at once attained by such a simple dodge; let us see how this agrees with theory.

#### The Theory of the Method.

In Fig. 1 let N be the luminosity curve of Vogel's photometer; the abscissæ be the numbers of the steps of the photometer, and the ordinates be the luminosity values of the individual degrees in fractions of the luminosity of the original light. Therefore, degree 0 has the luminosity of 1, and each succeed-

Fig. 1.

ing degree 1.27 that of the preceding one. If, for example, one had a negative of 10 degrees, its luminosities would be so reproduced by one printing on gum-bichromate that each photometer degree of the negative would correspond with the ordinates of the curve P. This curve P is obtained from Dr. Köster's curve for normal gum prints on sized paper which is also shown in slightly altered measurements, in that C to A is drawn in the co-ordinates of Fig. 1. That the ordinates of the curve P in Fig. 1 correspond to different photometer degrees than in Fig. 2 depends on the fact that by variation of exposure the curve P may be shifted throughout the whole of the photometer scale without altering the shape of the curve.\*

It will be seen that the curve P is quite different from the curve N; that especially the reproduction of the gradation in the shadows of the print is insufficient, and that from degrees  $7\frac{1}{2}$ –10 there will be no detail as these portions will be represented by bare white paper.

\* So far as we are aware, very little attention, if any, has been paid to Dr. Köster's work on the influence of development and the composition of the sensitive film on the gradation of gum print, and we hope to give a summary of his arguments shortly.—Eds. B.J.P.

If, however, there is added for every gradation of the negative an equal supplemental exposure of 0.3 of the original incident light in the clear portions of the negatives, and the time of exposure is reduced to three-quarters of the original, the luminosity under the clear glass parts of the negative, degree remains unchanged, whilst the luminosity under degree 5 of the negative now corresponds to photometer degree 5.

The distribution of luminosity under the negative would thus by the supplemental exposure be actually reduced from 10 to 5 degrees and would correspond now to the curve N1 in Fig. 1. If the exposure is now reduced still more, so that in the print only the piece A to B of Dr. Köster's curve of blackness, Fig. 2, is obtained, which exactly includes five degrees of the photometer, the degrees of blackness of the print under

Fig. 2.

the influence of the luminosity curve N1, will be reproduced by the curve P1, which only under degree 10 of the original negative gives blank whites, and in the other degrees agrees as completely as possible.

From these facts we may advance the following conclusions:

1. The supplemental exposure must be fairly strong in our numerical example about 0.3 of the luminosity under the bare glass of the negative.
2. The duration of exposure is not inconsiderably decreased in our case to more than one-fourth of the original time of exposure.
3. The luminosity curves are with correct treatment reproduced in a very perfect way.

#### A Practical Test.

The process is also proved by a practical test. The supplemental exposure was given by means of two incandescent lamps of 35 NK. at 100 volts, which, however, run at 110 volts, gave 75 NK. The two lamps were placed one on each side of the screen at a distance of 18 inches; to increase their action a semicylindrical reflector covered with white paper was used. The other arrangements were as already described. With this supplemental illumination much softer prints were obtained and a reduction of the exposure for the red and yellow prints to 15 minutes, and for the blue to 10 minutes was obtained.\*

Still even now the extreme reduction of the exposure is not reached. If the bichromated gum solution is allowed to stand for some time in the dark it becomes considerably more sensitive. The sensitised pigment and gum solution had, for instance, after seventy hours, about three times its original

\* It is a well-known fact that in the production of three-colour prints by contact printing on the ordinary trichrome carbon tissues, the red and yellow require longer exposures than the blue, one would naturally therefore expect the same law to hold good in enlarging.—Eds. B.J.P.

ness, so that with the supplemental exposure the yellow only required  $5\frac{1}{2}$  minutes to give an image equal in quality to that obtained with a fresh solution of gum in 15 minutes. In a second case a trichromatic negative intensified with gum was printed on a pigment mixture, which was made with gum solution 24 hours old. The supplemental exposure made with the above-mentioned lamps at a distance of inches from the middle of the picture; the exposures for yellow and red prints were 6 minutes, and for the blue prints. The quality of the image was perfect.

It is important to point out that the coating and colour must not be dried by heat before printing. I use a small electric fan. After development, however, each individual print should be dried by heat and then where possible be well exposed quite close to an arc lamp, so as to make sure that gum is quite insoluble and thus be able to bear the coating distributing brushes. It was soon found that in quick drying this was not attained by cold drying. Development was effected with a rose.

It should be further noted that the supplemental exposure helps to overcome the high inertia of the light sensitive bi-gum paper, as mentioned by Dr. Kösters, according to whose experience it is better to use an intense light rather than a weaker one in gum printing, and that sunlight is the best.

This recommendation, which is confirmed by Kosel, is based on the fact that negatives which will give good prints in sunlight will, if printed in a weak light, remain detailless in the high-lights, even if the shadows are much over-exposed. It is obvious that, in this case too, the disadvantage of the weak light may also be compensated by the supplemental exposure.

#### Focussing the Enlargements.

In enlarging trichromatic negatives direct there is yet another point to be considered, and that is the superposition of the images. It will be most convenient to fix rigidly all parts of the projection lantern, and to do as little focussing as possible even with the negative. The placing of the negative in the middle of the field of view is unavoidable, in which position it should be firmly fixed. All further focussing is best effected by moving the projection screen itself,\* which

is a small drawing board sliding both horizontally and vertically in grooves on the wall. The drawing board is first covered with drawing paper and the yellow negative, for instance, projected thereon in the required size. On the margins of the picture some sharp outlines should be looked for and traced with a sharp pencil. Then these outlines on these other images should also be made to correspond with the pencilling, before the sensitive paper is secured to the board. The sensitive paper should be fastened on the board with four drawing pins, which should be placed each time in the same holes, and old holes may be crossed over with the pencil.

There is no difficulty in obtaining the coincidence of the constituent images of unequal size, which may happen with nonsymmetrical objectives. It will be quite sufficient to give a very slight shift to the lens, which will scarcely alter sharpness. If perfect accuracy is desired then the whole apparatus may be shifted and the focus be readjusted.

The production of a three-colour print from the negatives, inclusive of focussing, preparing the paper, developing and drying the prints, requires altogether not more than  $1\frac{1}{2}$  hours.

The process leaves thus as regards the technical side nothing to be wished for. It may be objected that it reduces gum printing to the level of a silver print, since it excludes more or less the personal artistic treatment, which is attained by many gum workers. This I will not now dispute, although with the individual impressions there is still sufficient opportunity for the use of brush and local development, and certainly influence can be exerted on the tone of the picture by choice of the supplemental lighting and time of exposure.

But even if this is unsatisfactory, my process may in any case be useful to scientific photography, for which correct reproduction is the principal thing, and feeling and artistic treatment quite subsidiary. There is no doubt that three-colour printing in this department of photography is of the highest importance, and that up to the present the difficulty and complications of this process has limited its use.

RICHARD HEICKE.

\* If the original negatives are all of the same size and small there should not be the slightest difficulty in fixing them in true-up wooden frames, and accurate superposition of the images obtained precisely in the same way as is used in a triple dissolving lantern. For the necessity of focussing each image can only be requisite when the images are not the same size.—Ems. B.J.P.

## THE USE OF THE SPECTROSCOPE.

The following notes are written with the hope that they may help to define some of the very elementary facts connected with the spectroscopic, an instrument which has lately come more prominently to the front in photographic circles. Being purely elementary, many statements must necessarily be made which, to the expert, will appear utterly trivial, and in some cases even misleading, because essential data for higher work are omitted. As, however, it is to the absolute beginner, the one who has never handled a spectroscopic, that these articles are addressed in the hope that they may lead him to comprehend much of what now appears in the journals on spectroscopy and to experiment for himself, the expert worker must excuse such things by.

There is a well-known story to the effect that a candidate for an examination for physics defined a spectroscopic as "a collection of bits of glass in a brass tube." This may or may not be a true description, as will be seen later; but it would rather define it as an instrument by means of which one can conveniently make and observe a spectrum. Now, a spectrum may be most familiarly described as a "rainbow." Everyone has seen after a sudden rain storm a brilliant arch across the sky, comprising practically red, orange, yellow,

green, blue, and violet. This is a spectrum produced by the dispersion of the sun's light by means of the drops of rain.

It is unnecessary to give a figure explaining what is meant by the "dispersion" of light. This is to be found in every elementary book on optics and many elementary books on photography, where one finds the familiar prism or triangular piece of glass, with the homogeneous beam of white light entering the same, and emerging therefrom split up into a rainbow or spectrum.

When we use one or more brass tubes or other opaque media so as to limit the light reaching the prism, we can obtain a spectrum which is unmixed with white light, which is not the case with the rainbow, and we at once see that the colours are extremely brilliant. If we use daylight, under certain conditions, or gaslight we shall find that the spectrum is a ribbon of colours, starting with deep red and gradually shading off into orange, this into yellow, and thence into green, greenish blue, bluish green, blue, bluish violet, into pure violet.

It will be noted here that there are two terms used, "greenish blue" and "bluish green," which require a little explanation, for such terms are very common. The rule is to denote the

hue or tint of colour when not pure by a compound term, the first word of which shall give the predominant colour. Thus, in the first case just cited, "greenish blue" means a mixture of green and blue, in which green predominates. Exactly in the same way we may talk of a red-orange or an orange-red, the former having a preponderance of red and the latter a preponderance of orange, but both being orange.

### Mapping the Spectrum.

If when we use a spectroscope we limit the white light falling on the prism to a very narrow slice or line, by means of what is technically called a "slit," we shall find on examining diffused daylight or sunlight that now our spectrum, instead of being a continuous and unbroken ribbon of colours, is broken up by innumerable transverse black lines, some fairly distinct and others extremely fine and faint. These lines are known as the Fraunhofer lines, although actually discovered by Wollaston in 1802; but it was Fraunhofer who set to work to map these lines out, and he discovered that two black lines in the solar spectrum corresponded with the two bright yellow lines given by burning sodium. It was by Kirchhoff and Bunsen that the fundamental facts of the coincidence of the black lines in the spectrum of the sun with terrestrial metals were established.

Fraunhofer designated some of the most striking lines by the first letters of the alphabet; and, reading from left to right; as in the usual way, we have A in the extreme red, B in the deep red, C in the reddish orange, D in the orange (or, as it is generally called, the yellow), E in the green, "little b" in the green, F in the green-blue, G in the deep blue, and H in the violet.

These lines are practically the only ones that we need trouble ourselves with, and they may be likened to milestones on the road, for they tell us exactly where we are. For instance, supposing we have either a diagram or a coloured chart of the spectrum with these lines marked, and we are told that a certain plate is sensitive to D&E, we know that the plate is sensitive to violet and blue, and also to green and yellowish green. Precisely in the same way we know that when anyone talks of a panchromatic plate sensitive to C&D that it is sensitive to yellowish orange.

Another method of defining a particular part or colour of the spectrum is by naming the wave-length of the light. This may be done in three ways. Thus, taking what is known as the D line, we may express the length of the wave in thousandths of a millimetre, expressed by the Greek  $\mu$ , and it would then be  $\lambda 0.58916 \mu$ ; or in millionths of a millimetre, expressed by  $m\mu$  and it would be then  $\lambda 589.616 m\mu$ , or, more briefly,  $\lambda 589$ ; or we may write it as  $5896.16 \text{ A.U.}$  or  $t.m.$  A.U. stands for Angström Unit, and is named after Angström, who mapped and measured the visible spectrum from A to H. His map is usually called the Normal Solar Spectrum, and was published in 1868. In making it, the unit was a ten-millionth of a millimetre, or  $t.m.$  For all photographic work the expression  $\lambda 589$  is quite sufficient, for it will be seen later that for ordinary work the refinement of absolute measurements of wave-lengths to three or four places of decimals is absurd.

### The Anatomy of a Spectroscope.

A spectroscope consists of three essential parts—the collimator, the dispersing medium (which may be either a prism or a grating), and the telescope, the last being for photographic work replaced by a camera.

The essential parts of the collimator are the slit, which admits a narrow beam of light, and a lens which merely makes this parallel before falling on the prism. Unfortunately, a slit made by an optician, and such a one as is necessary for the highest work, is somewhat costly, but it is by no means a difficult matter to make one which will answer very satisfactorily

for photography. Brass is the easiest metal to use, and printer's brass rule, about one-sixteenth of an inch thick, answers well. One edge must be bevelled off, first with a file and then on a stone, to a knife-edge; the brass should then be cut in two and the two bevelled edges placed together, with the bevel inside. The actual size of the slit depends upon the size of the lenses and prisms, and, roughly, the following will be correct: For a 3in. diameter lens,  $\frac{1}{16}$  in.; for 2in. lens,  $\frac{1}{8}$  in.; for  $1\frac{1}{2}$  in.,  $\frac{1}{16}$  in.; and for a 1in.,  $\frac{1}{32}$ ths of an inch.

One of the pieces of brass should be screwed or soldered on a flat plate of brass, and the other left free, so that it can move on slides or grooves. It can either be actuated by a screw or can be just shifted with the fingers. There is no necessity for this screw to be a micrometer, for a fine square-ended screw, as used for electrical work answers perfectly.

The slit must be affixed to a brass tube, or, what is better for photographic work, a wooden box, as this simplifies matters considerably. At the other end of the box should be affixed the lens, the diameter of which should be equal to the height of the prism, or half as much again. Ordinary landscape lenses can be used, without the diaphragm. The focus may be almost anything over 7in., but 10in. or 12in. is most convenient.

As already stated, the purpose of the collimating lens is to render the beam of light passing through the slit parallel, and therefore the latter must be at the equivalent focus of the lens. This may be found by opening the jaws of the slit as wide as possible, placing a small piece of ground glass across the same, and focussing a distant object on it. When the exact focus is once found the position of slit and lens may be fixed, otherwise one or the other should be adjustable, but there is no advantage in this, provided the adjustment is once made.

The prism should have an angle of 60 deg., and such may be obtained at a very reasonable price made of flint glass, which is better than crown, as the dispersion is greater. It would be possible to use a hollow prism bottle filled with carbon bisulphide, but the practice cannot be recommended, because of the convection currents in it.

The prism must be supported on a stand opposite the centre of the collimator lens, and with its side parallel to the slit. There is a particular position for the prism with respect to the lens, which is the best to use. It is known as the angle of "minimum deviation," a term which will be explained later. The prism should be about 1in. from the outside face of the lens.

The camera lens will be naturally that with which the operator is in the habit of working, and may be either landscape or a doublet. The length of the spectrum is dependent on the dispersion of the prism and the focus of lens. The lens should be placed about an inch from the prism face, and of course level with it.

When the whole apparatus has been set up the camera must be shifted towards the base of the prism till the spectrum is seen, because, as is well known a prism refracts as well as disperses the light, and the refraction is always towards its base. When the spectrum is seen centrally on the ground glass of the camera it may be focussed till its edges are sharp; we may then burn some salt in a bunsen burner in front of the slit and focus the bright yellow line.

We now come to the operation of setting the prism at the angle of minimum deviation. This is most easily done with the salt and bunsen flame. The prism should be turned on its support first in one direction and then in the other, and the yellow line will be seen to move, and then it reaches a point at which it turns back again; this point where it begins to turn back shows that the prism is at the angle of minimum deviation. This is most easily done with the salt and bunsen flame. The prism should be turned on its support first in one direction and then in the other, and the yellow line will be seen

move, and then it reaches a point at which it turns back in; this point where it begins to turn back shows that the spectrum is at the angle of minimum deviation, and it is as well drawn pencil lines round the base of the prism on the support, so that the prism may always be set in the correct position. Instead of salt we may, of course, use magnesium ribbon, and the minimum deviation for the bright green rays.

Provided the length of the spectrum is not too great, practically all the lines will be in focus at once, or an almost easier method is to see that the spectrum is the same width from the

red to the violet. If it is not, the swing back or side swing must be used.

The above are the essentials for a prism spectroscope, with the exception of details as to the slit width; this will be dealt with later. There are, however, serious objections to the use of the prism, and the apparatus is clumsy and takes up room, and unless the whole is firmly clamped together on a solid support there is great chance of parts shifting and of vibration. Much more compact and handier apparatus will be described hereafter.

E. J. WALL, F.R.P.S.

## THE THEORY AND PRACTICE OF INTENSIFICATION.

### III.

THOUGH any particular intensifier cannot be definitely recommended for each individual negative, a reference list of the various modern formulæ is desirable. The reason that the comparison of two intensifiers will not always hold good will readily be seen from the following example. The effects on gradation of two plates intensified, one with mercury and ammonia, the other with chromate and hydroquinone-soda, may vary in their relation, because the time allowed for bleaching the mercurial case will bring about a different effect according as it varies; a very short bleaching may convert the shadow all into the white compound substances, the high-lights being superficially bleached, whilst with a prolonged bleaching shadows may be still only bleached, and the high-lights verted throughout. The result in each case would vary as regards gradation in the intensified negative.

The bleaching bath for all mercurial purposes may be the one, as follows:—

Mercuric chloride .....	105 grs. or 6.8 grms.
Ammonium chloride .....	42 grs. or 2.7 grms.
Water .....	8 ozs. or 250 c.c.s.

Assuming that a constant time be allowed for bleaching, the following reblacking baths are recommended:—

For normal, or under-exposed, negatives, a 10 per cent. solution of ammonia.

For weak, or over-exposed negatives:—

Hypo (or, ammonium thiosulphate) .....	4 ozs. or 60 grms.
Water .....	20 ozs. or 300 c.c.s.

A 10 per cent. solution of sodium sulphite is suitable for over-exposed negatives, when bleached for a short time only, or for flat over-exposed negatives when thoroughly bleached (3-5 minutes at 60 deg. Fahr.).

For normally-exposed, under-developed negatives, a short bleaching followed by ammonia, may be alternated with a longer bleaching, and redevelopment with a 5 per cent. solution of acetone sulphite.

#### MERCURIC IODIDE.

There are two ways of using mercuric iodide. The first is to prepare two solutions as follows:—

A.—Mercuric chloride .....	60 grs. or 4 grms.
Water .....	7 ozs. or 200 c.c.s.
B.—Potassium iodide .....	180 grs. or 12 grms.
Water .....	3 ozs. or 85 c.c.s.

Four sufficient B into the A to quite redissolve the red precipitate at first formed. Mix one part of this solution with three parts of water, and immerse the negative in this until sufficiently intensified. Then rinse well and clear in 5 per cent. solution.

The alternative method is to make up the following:—

Mercuric iodide .....	15 grs. or 1 gm.
Sodium sulphite .....	300 grs. or 20 grms.
Water .....	3½ ozs. or 100 c.c.s.

The plate is left in this solution until sufficiently dense, then washed (for not too long a time).

Mercuric iodide gives a result similar to that produced by mercury and ammonia.

#### COPPER BROMIDE.

Equal parts of the two following solutions are mixed:—

A.—Copper sulphate .....	30 grs. or 2 grms.
Water .....	3½ ozs. or 100 c.c.s.
B.—Potassium bromide .....	30 grs. or 2 grms.
Water .....	3½ ozs. or 100 c.c.s.

The well washed negative is bleached in this, rinsed for ten minutes, then reblacked in

Water .....	3½ ozs. or 100 c.c.s.
Silver nitrate .....	30 grs. or 2 grms.
or,	
Amm. sulphide .....	1 drm. or 4 c.c.s.

#### LEAD.

Lead nitrate .....	75 grs. or 5 grms.
Pot. ferricyanide .....	120 grs. or 8 grms.
Glacial acetic acid .....	1 drm. or 4 c.c.s.
Distilled water .....	3½ ozs. or 100 c.c.s.

The negative is bleached in the above bath, and then washed in water containing a trace of nitric acid. It is next reblacked in either weak ammonia or Schlippe's salt solution.

Both lead and copper increase the harshness of the negative, the former being chiefly employed in process negative making.

#### URANIUM.

Two solutions are advisable, as follows:—

A.—Uranium nitrate .....	30 grs. or 2 grms.
Glacial acetic acid .....	5 to 10 drops.
Water .....	3½ ozs. or 100 c.c.s.
B.—Potassium ferricyanide .....	30 grs. or 2 grms.
Water .....	3½ ozs. or 100 c.c.s.

For under-exposed negatives use three parts of A to two of B; if the negative be over-exposed, use three parts of B to two of A. If the whites become discoloured, soak the intensified negative in 5 per cent. ammonium sulphocyanide solution.

#### CHROMATE.

"Bleach" the negative with a solution of

Potassium chromate .....	30 grs. or 2 grms.
Hydrochloric acid .....	15 mms. or 1 c.c.
Water .....	3½ ozs. or 100 c.c.s.

Redevelop—after a short washing—with hydroquinone, or metol-hydroquinone-soda.

#### PERMANGANATE.

Soak the negative for one to three minutes in a freshly made solution of

Potassium permanganate	30 grs. or 2 gms.
Hydrochloric acid	5 mns. or 4 c.ms.
Water	3½ ozs. or 100 c.cs.

Next wash for two or three minutes only, then redevelop as with chromium.

#### REHALOGENISING BATH.

Bleach the plate in the following bath:—

Copper chloride	30 grs. or 2 gms.
Hydrochloric acid	30 mns. or 2 c.cs.
Water	3½ ozs. or 100 c.cs.

Wash well, and redevelop with amidol or glycin for preference. If it be desired to reduce contrast, only carry on development until the shadows are reblackedened; then quickly fix in hypo. The high-lights can thus be actually reduced whilst the half-tones and shadow-details are intensified.

T. THORNE BAKER, F.C.S.

## FOREIGN NOTES AND NEWS.

### Marginal Fog.

Dr. STOLZE states, in the current number of "Das Atelier des Photographen," that marginal fog on plates is due to radiations from the packing materials. Incidentally he points out that ammonia emulsions are much more liable to this than acid boiled emulsions, and this is due to traces of ammonia being tenaciously held by the gelatine. To render this harmless he suggests that carbonic acid should be pumped through the emulsion of carbonic acid water be added to the same, so as to form the true ammonium carbonate. If the plates are already coated, then it is sufficient to fume the plates with carbonic acid [He does not state whether the plates are to be wet or dry.—Eds., B.J.P.], and advises that plates intended for the tropics should be packed in boxes filled with carbonic acid instead of air. Plates kept in metal boxes at fairly high temperatures for varying periods of time showed marginal fog, and more at the edges of the glass than these edges which were cut from a larger plate. From this curious fact he argues that the effect is due to "rays."

In the BRITISH JOURNAL for December 22, 1905, page 1008, an abstract is given of Dr. Homalka's experiments on this subject, in which he proves that marginal fog is due to a diffusion of the salts from the edge towards the middle of the plate, the chief salt being traces of the alkaline bromide used in the manufacture of the emulsion, which thus keeps the centres free from fog.

### Carbon Tetrachloride Varnishes.

Valenta suggests in the current number of the "Korrespondenz" the use of carbon tetrachloride as a solvent for various resins which will give good cold negative varnishes. Carbon tetrachloride,  $\text{CCl}_4$ , is a colourless, pleasant-smelling heavy liquid of great dispersive power, which boils at 138deg. F. The specific gravity is 1.63; it is mixable with alcohol and ether, insoluble in water, and dissolves oils and various resins fairly easily (and costs pure about 1s. per lb.—Eds., B.J.P.) A solution of 5 to 10 parts of gum dammar in 100 parts of carbon tetrachloride gives, after filtration, a clear solution, which, poured on a glass plate, leaves behind, after evaporation of the solvent, an absolutely clear, hard, and firm film of varnish. This dammar varnish is excellent for gelatine negatives as a cold varnish, and may also be used in suitable concentration for varnishing collodion plates.

Mastic also gives a useful varnish, although it is less soluble than dammar. To make such a varnish 5 parts of mastic should be dissolved by the aid of heat in 80 parts of carbon tetrachloride, allowed to cool, and then filtered, and the varnish kept in well-corked bottles. Both these varnishes give films which, when quite hard, take the pencil well. It is difficult to make a shellac varnish with carbon tetrachloride, as this resin is very insoluble in it.

### Yellow Fog in Bromide Prints.

Namias states that bromide prints and plates fixed in a weak fixing bath frequently show a slight yellow fog or stain, due to small traces of the developer, reducing very minute traces of silver, and this defect is particularly noticeable in the shadows of the negatives and whites of the print. To prevent this, he recommends that fixation should be effected in almost saturated solutions of hypo, that 5 per cent. of boric acid should be added to the bath, so as to prevent the action of the developer, and that fixation should

always be done in the dark. There is not the slightest danger of any reducing action in such a strong solution of hypo unless the prints or plates are left in for two hours.

### Photographing Writing and Printed Matter.

Dr. Wiedeman gives, in the "Zentralblatt für Bibliothekswesen," a very simple method of obtaining quickly a photograph of a manuscript or printed matter, and whilst this idea has been used for some years, it may be useful to draw attention to it. It entirely obviates the making of a print, as for such purposes as it is intended, for it is perfectly immaterial whether the written or printed characters be black or white, so long as they are distinctly legible. A reversing mirror is placed in front of the lens, and the object is photographed

on to bromide paper, which is then developed in the usual way, so that a black line appears as white on a black ground. The position of camera, mirror, and object is shown in the following diagram, in which C is the camera, L the lens, S the mirror, and B the book, which obviously lies flat on the table. This method has been in use in the libraries of Rome, Paris, London, etc., and in Paris the bromide paper is used in rolls, and all exposures developed at once. It is obvious that this method of working is particularly valuable when a manuscript can only be retained for a short time.

### The Red Filter in Three-colour Work.

Mr. Thorne Baker, in the "Korrespondenz," points out that the exposure through the red filter is the longest, and that it is very desirable to reduce it as far as possible. Homocol, pinachrome, and pinacyanol bathed plates show a better red sensitiveness than when the dyes are added to the emulsion, but still in these cases there is need of a red filter that cuts the exposure down as much as possible. In order to attain a good reproduction of the blue-green, green, and yellowish-green in the colour print, it is necessary that the transmitted spectrum of the red filter should still contain some green, the luminosity of which appears abruptly cut off at  $\lambda$  5,750, which, however, with longer exposures, gradually increases till at about  $\lambda$  4,750 it is completely extinguished. Naturally the latter region will only be faintly reproduced even with longer exposure. A sheet of glass should be coated with a 5 per cent. solution of gelatine and dried, and then soaked in a solution of

Croceine scarlet R	10 parts.
Tartrazine	0.05 parts.
Water	1,000 parts.

till the requisite degree of staining is obtained. The dye bath must be made up 24 hours before use, well shaken, and then filtered twice. The stained plate must be rinsed under the tap, and quickly dried at about 75deg. F., otherwise the dye will crystallise out. Croceine scarlet R. is made by the Bayer Company, and it permits of very

rt exposures being given. The author does not, however, give information as to how short the exposure is with any plate.

#### Acid Bisulphite Lye.

Amias has analysed the commercial acid sulphite lye, and finds it consists of 25 per cent. of sodium sulphite, 10 per cent. of sulphurous acid, and 0.7 per cent. of sulphate of soda. This, being into consideration the small proportion of sulphate, is much better than commercial sodium sulphite, and he suggests, therefore, that it should be used instead of the sulphite and the free acid neutralised with caustic or carbonate of soda. If 150 parts of stic soda are added to 1,000 parts of acid lye, the result will

represent 400 parts of anhydrous or 800 parts of crystallised sodium sulphite. Instead of neutralising beforehand, the lye may be added to the developer and the carbonate of soda increased, and he gives the following as a suitable formula:—

Acid sulphite lye (32 deg. Be.) ...	60 parts.
Sodium carbonate anhydrous .....	100 parts.
Potassium bromide .....	1-2 parts.
Hydroquinone .....	7 parts.
Metol .....	1 parts.
Water .....	1,000 parts.

This reduces the cost of the sulphite considerably.

## PORTRAITURE BY R. DÜHRKOOP.

second house exhibition at the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY opened on Tuesday last, and will remain open till May 26, being open free to visitors from 10.30 to 4.30 every day of the week except Saturdays, when the hours are 10.30 to 12.30. I shall not refer at length to the collection of Herr Dührkoop's portraiture which has been brought together until next week, when a critique will appear by Mr. F. C. Tilney. We may, however, quote a few notices of the exhibition, which reach us as we go to press.

The "Times" says:—Herr Dührkoop has devoted many years to making a series of portraits of the celebrated people of his town, and these, reproduced by photography from plates of the photographer's own making, may be seen in a large portfolio in the gallery. They are all vigorous and characteristic, one or two rising to a high level; and the ruff and roan in which nearly every celebrated man (there are very few celebrated women in Hamburg) wears have a valuable pictorial quality; the effect of turning over the many sheets of the portfolio is to the lack of variety in the subjects. That feeling can instantly be removed by a glance at the walls, which are hung with original photographs. There are a few celebrated men here, too—No. 4, a portrait of "Dehmel (Poet)," and No. 72, a strong study of Herr Dührkoop—may be especially noticed; but it is the photographs of children which will most attract the visitor. Herr Dührkoop, as Mr. F. C. Tilney tells us, though a man of over fifty, "is content to dance antic before his youthful sitters," and his efforts have their reward. These child-studies are delightfully natural, fresh and spontaneous. Sometimes, as in Nos. 45 and 49, the child is merely lying still and looking straight at the camera; sometimes two or three are building bricks, or playing games, as in No. 26 (a very pleasing composition); in one case (No. 25) two babies are at breakfast; in another (No. 18) there is a baby in bed laughing up at its mother; in several the child is being kissed or held close in a hug. There are constant variety and constant individuality in these portraits of children which are not often found in the work of the child photographer. Old women, too, make good subjects for Herr

Dührkoop; notice No. 43, the poet, "Elise Averdick," and No. 75, "Mme. Zacharias," and, to descend the social scale, No. 34, "Gossip," and others, which show very natural studies of old peasant women. Herr Dührkoop can make mistakes, as in the very commonplace "The Big Hat" (No. 14), and the unpleasant "Recollection" (No. 45), in which the lady appears to be holding two telephone receivers to her ears. He sometimes poses his subjects in too theatrical a manner. But his accomplishment is high. The interior (No. 7) must have been very difficult and is very charming. So is No. 39, a gum print, "In the Doorway," and many of the figure studies, though called by grandiloquent names, are remarkable for their naturalness and intimacy.

"The Pall Mall Gazette," in its "Photographic Notes," by "J. M. B.," writes:—The collection of portraits by a Hamburg professional that are now being shown at the office of THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, will, I feel sure, be universally admitted to be a remarkable show. Herr R. Dührkoop is a professional of long experience, and the pictures now on show are, we are told, such as he turns out in the ordinary way of business. If that is so, one cannot help thinking that the Hamburg professional's patrons require, and insist on having, a very much better portrait from the artistic point of view than do our people over here. At any rate, these pictures, with a few minor exceptions, have a quality about them that makes them quite different from the work of the average high-class professional. There seems to be very little retouching or "faking" of any kind about this work; it is just good straightforward photography, but wonderfully good of its kind. In his portraiture of men the photographer has had some striking sitters, and has caught their personality to a surprising degree. And yet I like him better in his presentation of children. In some of this class of work he has given us a rendering of his little sitters that is quite fresh, and yet perfectly natural without, while in all his work his command over the processes of carbon, gum and platinum enables him to make the most of what must, in the first place, be very fine negatives.

## THE ARTIST, THE PHOTOGRAPHER, AND THE MODEL.

[A paper read before the Photographic Society of Philadelphia.]

A painter always uses models, and though he may exercise his imagination in delineating them upon his canvas, there is always a certain amount of realism about his productions from the living object which enables us to recognise the special individual he has employed in his studio. And so, if we examine the work of noteworthy photographers, we shall discover that it is not so much the technical qualities which attract us, but the skill displayed in lighting, posing, and managing the model. As a general rule the photographer is anxious about the slant of his studio light; he is urgent in his inquiries as to what kind of curtain to employ; will follow implicitly the directions laid down in some photographic magazine on the advantage of side light, or on the super-necessity of top illumination

for artistic effect or 45 degree angle of illumination; how far the subject should be placed from the source of illumination; what height the camera ought to be; what inclination, etc. All this is mechanical, and he ought to know all about it before he puts his model before the camera.

A well appointed studio, in fact the most scientifically constructed studio, is, after all, only a means to an end in securing artistic effect. A cut and dried method of professional photography is the bane of the profession. There is more originality and a greater display of effective illumination to be found in amateur work, simply because nine times out of ten the amateur is obliged to work under constrained conditions of illumination. He has that as a fixed and un-

alterable quantity, and so his whole attention is upon his model. His thought is on his subject, and the light is made to do his bidding, and the result is generally more pleasing to the painter than the faultless technique and skilled lighting of the professional. The professional cannot understand the reason for this preference of the painter for the crude productions, as he calls them, of the amateur over his carefully but conventionally posed subjects.

#### Professional v. Sympathetic Model.

Another point, too, in which the amateur is more in line with the painter than is the professional is the employment of models. The only desire of the amateur is the realisation of the idea he has in his mind, and the sitter is generally accessory to his striving, and so in a measure contributory.

The painter, as we say, always uses professional models. It is true these models, as a class, have not the intelligence of the average sitter to the amateur, but by their experience and training they have acquired a certain amount of pliancy, and are capable of being moulded, so to say, to the conception of the artist—in reality becoming a part of the painter's self.

And now the question arises, which is preferable, the model who follows the profession as a means of livelihood, who becomes nothing but the clay in the hand of the artist, and aims to be and to do nothing but what is desired, or the casually selected model, the friend and acquaintance of the photographer who may be a very intelligent person, capable of high thought and possessed of keen artistic perception; and who may desire intently to carry out the conception demanded by the picture?

Unfortunately, this role of the models though apparently a very easy one, is not so easily played as one might imagine.

It is one thing to take a histrionic attitude and to have your soul filled with the theme for the delectation of an audience, and another to pose before the camera so as to give sentiment, life and animation to the image on the ground glass. The histrionic pose is a dead failure in photographic art. Any painter will tell you it takes certain characteristics to make a model.

The class model or professional model is really a certain social differentiation, and on this account is to be preferred to the haphazard selected model or self-conscious sitter. We frequently hear the remarks of people when pleased with a well conceived picture, "What a clever model," or something of the kind, implying that the artist was dependent altogether on the model for his success.

Now, nothing is more fatal to success in portraiture or genre than to have a model who is clever or over-intelligent. It is more fortunate to have one who, while possessed of these qualities, is at the same time obedient and pliant.

#### The Virtue of Compliance of the Model.

Everyone knows that actors are the worst possible agents in the hands of an intelligent photographer. Dramatic action is appropriate with its proper stage settings, but it is out of place in a picture—it makes things look stagy. And yet actors, as a class, are

far above the artist's model in intelligence and education, but it is just the self-conscious knowledge which makes them spoil the picture. A photographer who has no idea of his own will succeed better with an actor than with an artist's model, the reason being obvious. But when trying to materialise some idea of his own in a picture his model had better be kept in ignorance of his intention. All that is demanded is compliance, and this can only be effectively secured by employment of trained, hired models.

Even the expression of the subject is better secured by use of the paid model. The photographer is bound to get nothing but a histrionic pose by asking a model to assume a trait not inherent in their character. Even Reynolds did not succeed as well with Mrs. Siddons as the "Tragic Muse" as with some of his other work, notably the "Duchess of Devonshire." Any one can see in this delightful composition of the great painter how he has utilised the unconscious moment of the model, when her every thought was centred upon the little child she is holding at arm's length.

But let the photographer be within the moderation of nature and not strive to get agonising expressions. Never attempt a subject which cannot be followed out with a model. Be natural, and you shall enter the kingdom of art even if ye may be cast out of the salon.

Never advertise the method by which you secured your result, neither to the model nor to the readers of art magazines. Be magnanimous and let the model imagine she is the be-all and the end-all of your success.

Let us photographers follow in the line of the painters and not be so ambitious, or, rather more forcibly put, self-conceited, by carving out new paths in art for ourselves which the painter fears to tread. Let us study lighting and posing and draping from the painters' art, with the aid of the complaint trained model, a girl who is perfectly at her ease while with the photographer, who knows just how far to appreciate his chaff and who doesn't take offence easily or get tired or impatient, or knows better than the artist; whose ambition is to please and to be accounted a success at her trade. One who will do anything desired to carry out the artist's idea about which *per se* she knows nothing and cares less. Such a subject will be more likely to give the picture success than the young lady of your acquaintance whose every movement you consider a favour, and tell her so, every change or condescension, and from whom you are from time to time supplied with distracting suggestions about the *motif*.

Then the chance of selection is wider amongst the ranks of the Tribllys. There are more comely faces and graceful figures willing to have their charms portrayed, and the photographer is not compelled as he frequently is when a friend has posed for him, and he has achieved something beautiful, to hide his picture and surreptitiously exhibit it to only a few choice friends with fear and trembling lest he offend the fair original.

Therefore, in conclusion, I want to inculcate, first, have a definite idea as to what you intend to embody in your picture, then search out the model or models best suited and go to the lists of the professional rather than to the circle of your friends. JOHN BARTLETT.

A PHOTOGRAPHIC Survey of Sussex.—Mr. J. C. Stenning, of Steel Cross House, near Tunbridge Wells, is the hon. secretary of the Photographic Survey of Sussex, the second annual report of which has now been issued. The report records two exhibitions, one held at the Eastbourne Public Library in July, the other at Hastings Museum in August. Both were well attended, and the respective curators reported that the photographs were of much interest to visitors. There are several new subscribers to the Survey. The committee draws the attention of any who possess old photographic or scrap albums, old negatives or photographs of buildings or of other antiquities in the country, to the service that can be rendered by their lending them for the purpose of copying; any such articles sent to the hon. secretary will be copied and carefully returned. Negotiations are in progress for placing the Survey on a better and wider basis, and thus rendering it more useful and permanent, and also with the view of making the collections of photographs, lantern slides, etc., accessible to all interested. Should this alteration be effected, notice will be given to subscribers and contributors; in the meantime the committee appeals to amateur photographers interested in the work of the Survey to take any of the vacant sections, three miles by two

miles, into which the county has been mapped out for the purposes of the Survey, and to this end the hon. secretary invites correspondence.

Our Leaders in the North.—The "Newcastle Weekly Chronicle," in its photographic notes commences a series of brief biographies with that of Mr. Arthur Payne, well known by his writings no doubt to many of our readers, and a technical director of the factory of Mawson and Swan, Newcastle. We will spare Mr. Payne's blushes by recapitulating his many labours and achievements, yet we may quote the local tribute to his work—the establishment of the Northumberland and Durham Federation. "A work of Mr. Payne's that has perhaps been of most benefit to this district was the formation of the Federation some four or five years ago. His commanding position to-day is the outcome of most arduous labour, freely given for the good of others. He held the position of secretary until a year ago, when upon retiring he was made a life member of the Federation."

The death took place on Tuesday in last week at 6, St. Margaret's Road, Plumstead, of Mr. Dutton, at the age of fifty-seven years. Deceased was a partner in the firm of Messrs. Schreiber and Dutton, photographers.

Patent News.

Process patents—applications and specifications—are treated in *Photo Mechanical Notes*."

The following applications for patents were made between April 2 and 7:—

**REPRODUCING.**—No. 7,935. Improvements in reproducing pictures by reprinting an original picture that has been treated under hydrogen peroxide. A. G. Bloxam, Birkbeck Bank Chambers, London, for Veire Photographische Gesellschaft, Germany.

**COPIING APPARATUS.**—No. 8,239. Improvements in photograph-copying apparatus. Heinrich Koller and Samuel Löw, 65, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**VELOPES.**—No. 13,475, 1905. The invention consists of a cover in one piece of paper or of fabric such as chintz or silk, satin, muslin. The front and back are joined together at one end, whilst the opposite end of the front may have a flap extending from it. Other flaps are provided along each side of the front. In the central part of the front is a large opening which on the inside is closed by a flexible sheet of talc cemented at its edges to the front inner face. The back is doubled over to lie against the inner face of the front, and the side flaps of the front are pasted over the back. The flap at the end of the front may also when a photograph has been placed into the cover, be either pasted down to the back or tucked into the cover's open end. When a photograph has been placed into the cover it can, if desired, be retained centrally with the talc-covered opening by brass pins or fasteners passed through it at its corners and through the cover. Janie Lambert, Telham Court, Battle, Sussex.

**SHUTTERS.**—No. 12,030, 1905. The invention provides an improved means of forming a direct light-proof joint between the shutter and the lens partition by the following means: The shutter, which may be of the sliding plate or quadrant plate, or other suitable pattern, is fixed on the inner surface of the front panel, and enclosed by means of a metal cover (hereinafter called the cover) in such a manner as to leave sufficient space for the free play of all the working parts, the cover being turned down on each of its four sides, and provided with suitable flanges for the purpose of attaching it to the front panel. This cover is provided with a circular opening to correspond with the exposure aperture in the front panel of the camera, and around this opening is formed a series of concentric depressions or corrugations. Over the lens, which is fixed on the intermediate partition, is fixed a metal or wood tube, which extends forward towards the cover, but is not quite long enough to form contact therewith when the front panel is closed. The outer end of this tube carries a disc, which is pressed forward by means of an enclosed spiral or other spring, and prevented from being thrust too far by means of a flange formed on the front face of the tube. The disc is provided with a central aperture around which a series of concentric corrugations are formed, and projects beyond the tube sufficient to form a yielding contact with the cover when the front panel is closed, the corrugations on the disc being so formed that they engage with those on the cover and form a perfectly light-proof connection. The shutter release projects through an opening in the side of cover, and a corresponding space is made in the side of the camera body to allow of the necessary movement when operating the shutter. It will be seen that the improvement removes all possibility of light entering the camera through reflections from inner surfaces, for, notwithstanding that there may be a considerable quantity find its way between the front panel and the inner partition by means of fine apertures or an imperfectly fitting front, it is entirely prevented from passing through the lens and fogging the plates by reason of the contact of the corrugated surfaces. By

varying the construction of the device the spring operated disc could be applied to the shutter cover, and a corresponding series of corrugations be made on the face of the lens tube, or the surfaces of these parts could be plain, without corrugations, and covered with velvet, leather, or other suitable material for the purpose of forming a light-tight joint at this juncture. By a further modification the joint could be made by means of a fixed flange on one part working in a channel or making contact with a yielding material, such as velvet, on the other part. When adopting the corrugated spring disc, as before described, its diameter is adjusted so as to allow of a moderate amount of side play in the metal or other tube for the purpose of accommodating the fit of the two corrugated surfaces in case the openings in same are not quite concentric. Herbert Holmes, Tudor Works, Tudor Road, Hackney; and Houghtons, Ltd., 88 and 89, High Holborn, London, W.C.

**SHUTTERS.**—No. 25,237. Certain of the claims set forth are: A photographic shutter, consisting of two gold-mounted plates, or of two plates, each with an exposing aperture, revolving on the same centre, and both revolving together during the whole period of exposure in conjunction with means whereby one of the plates is stationary and the other revolving during the process of winding; a shutter as above having means for altering the angular position of the two plates by a gearing connected to one of them, the gearing being mounted on a separate centre from that of the

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

plates, and having a catch or catches to hold the other of the plates stationary while the change is being made. In a photographic shutter as claimed in above, the combination of means whereby one only of the plates is revolved for a certain distance for the purpose of winding, and can then be revolved somewhat more or less than the distance required for winding in order to vary the size of the exposing aperture, which opens the lens and which can be further revolved to a greater or less extent in order to bring into action catches for the purpose of stopping the revolving plates, while the exposing aperture is opposite the lens in order to make prolonged exposures. In a photographic shutter, as above claimed, the combination therewith of a set-off lever, which releases a projection on the driving device, and which, also by means of a supplementary lever, releases a projection on one of the revolving plates in order to make the exposure. The action of the shutter is as follows:—In order to wind the shutter, the milled head s is revolved clockwise. This carries with it the cog wheel e and the flanged sleeve f, which are all locked together by the pin s<sup>1</sup>. It also carries round the cup i, the dial h, the cap k, the sleeve nut g, and one end of the

driving spring *l*, and places this spring under tension. When the winder *a* has been revolved about half a revolution, the set-off lever *y* drops into the stop notch in the flange of the sleeve *f* and holds the shutter wound. During the course of winding, the speed plate *b*, which is geared to the winder, has been revolved anti-clockwise for a complete revolution while the shutter plate *a* has been retained in a stationary position by the pawls *v* and *w* acting on the projection *c*<sup>1</sup>, thereby avoiding opening the lens during winding. To make an exposure the set-off lever is pressed so as to lift the projection *y*<sup>1</sup> from the stop notch in the flange of the sleeve *f*. The winder is then driven round by the spring *l*, carrying round with it the speed plate *b*, and also the shutter plate *a*, because the latter is now free to move, the pawl *w* having been lifted by the set-off projection *y*<sup>2</sup>, and because it is held by friction to the speed plate *b*, so that the two revolve together. Thus when the shutter is set off or released, both plates, *a* and *b*, revolve for an entire revolution and uncover the lens aperture for a longer or shorter period, according to the size of the aperture in the said plates. Both the plates *a* and *b* are provided with apertures, which are preferably 180 degrees or thereabouts in their angular size, and it is evident that by varying the relative positions of the two plates, the angular size of the resultant aperture, formed by the two plates, may be reduced until it is a small slit. Figs. 3, 4, and 5 show the plates *a* and *b* in different relative positions. Fig. 3 shows the two plates superimposed, giving the maximum attainable aperture. Figs. 4 and 5 show them arranged to give smaller apertures. The variation of this aperture is obtained in the following manner: After the shutter is wound, the winder *s* may be slid outwardly along the cup *i* against the pressure of the spring *i*<sup>1</sup>, thus drawing the pin *s*<sup>1</sup> out of engagement with the flange of the sleeve *f*. It can then be revolved independently of the sleeve *f*, but it will not draw the pin *s*<sup>1</sup> sufficiently far out to disengage it from the cog wheel *e*, consequently its revolution also revolves the speed plate *b* by means of the cog-wheel *e*. In this way the shutter plate, being held stationary by the pawls *v* and *w*, the relative angular position of the plates *a* and *b* can be altered to any extent. The pin *s*<sup>1</sup> can be engaged in any one of the series of notches *f*<sup>3</sup>, thus locking the winder in different positions and leaving the plates *a* and *b* in definite relative angular positions before they revolve to make an exposure. Thus each of the notches *f*<sup>3</sup> corresponds to a different resultant aperture in the plates *a* and *b*, and a different duration of exposure is given by the revolution of the exposing plates, dependant upon which one of the notches *f*<sup>3</sup> the pin *s*<sup>1</sup> had been engaged in immediately before the exposure was made. The position of the winder *s*, with reference to the dial *h*, records the notch in use, and consequently the duration of exposure that is given, as the dial *h* is attached by means of the cap *k* to the cup *i*, which latter is attached to the flange of the sleeve *f* by the sleeve nut *g*. Conrad Beck and Horace Courthope Beck, 68, Cornhill, London, E.C.

**EXPOSING PLATES, ETC.**—No. 21,840, 1905. The invention relates to a method of successively exposing sensitive sheets (plates, films, etc.) in a suitable chamber by pulling the exposed sheets one after the other out of the exposing chamber into a collecting chamber. The invention does away with the necessity of providing a special chamber for gathering the exposed sheets, by allowing the light-tight envelope in which the sheets are enclosed before some are inserted into the exposing chamber to be also used as a collecting chamber for the sheets after exposure. Therefore the device comprises an exposing chamber and a package containing sensitive sheets having extensions, the package having a light-tight envelope adapted to be shifted on the sheets contained therein. The exposing or film changing chamber, shown in Fig. 1 has a cover *a* jointed thereto, this cover being provided at both ends with strips *b*, *c* of velvet or similar material. Opposite the strip *c* of the cover *a* is a strip *d*, fastened to the frame of the exposing chamber, so that the strips *c*, *d* are pressed together on closing the cover *a*. At the end of the exposing chamber, which is opposite the end carrying the strip *d*, the chamber is provided with a mouthpiece *e*, having a free passage. The film represented in Fig. 2 is designated *f*. The film is provided at both ends with unsensitive extensions, forming pulling strips *g*, *h*. The light-

tight cover enclosing a pile of films *f* is designated *i*. The cover *i* is shiftable on the pile of films; and for this purpose is provided at both ends with ribs or strips *k*, *k* and *l*, *l*, respectively of velvet or similar material surrounding passages for the pulling strips and the films, and to make a light-tight contact with opposite surfaces of the pile. The light-tight cover *i* of the film package is provided with a flap *m*, which may be grasped in order to shift the envelope *i* on the films. The use and operation of the devices described is as follows:—Assuming that the exposing chamber has been opened, as shown in Fig. 1 of the drawing,

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

then the film package, shown in Fig. 3, is inserted in such a manner that the flap *m* and the pulling strips *h* pass through the passage of the mouthpiece *e*. Now the cover *a* of the exposing chamber is closed, with the effect that the flaps *g* are squeezed between the ribs *c*, *d* of the exposing chamber; at the same time the rib *b* is pressed against the side wall of the mouthpiece *e*, so that the passage of such mouthpiece is compressed. Now one grasps the flap *m*, and at the same time the flaps *g*, and begins to pull, so that the light-tight cover *i* is shifted along the film pile and passes through the passage of the mouthpiece *e*. The movement of the cover *i* is limited by suitable stops, not represented on the drawing. Now the cover *i* has the position shown in Fig. 4, and compresses the strips *h* between its ribs *l*. The cover *i* may be turned over so as to contact with the cover of the exposing chamber, this being possible owing to the foldable nature of the material forming the mouthpiece *c*. If now a film has been exposed, and if it is desired to take it out of the exposing chamber and to place it in the collecting chamber which is formed by the cover *i*, then the operator grasps the pulling string or flap *h* of said film and pulls the film between the ribs *h* of the cover *i* into the hollow of the cover. This procedure is repeated as often as a film has been exposed within the exposing chamber. When the films in the exposing chamber, which originally in unexposed conditions were in the cover *i*, are all exposed and carried back into the cover *i*, then the apparatus is brought into a dark room and the cover *i* is removed from the exposing chamber and the films are taken out for development. Carl Paul Goertz, 10, Bismarck Allee, Grönewald, Berlin; and The Optische Anstalt C. P. Goertz, a.-G., Rheinstrasse, Friedenau, Berlin.

The following complete specification is open to public inspection before acceptance, under the Patents Act, 1901:—

**CHANGING PLATES.**—No. 24,431, 1905. Apparatus for carrying or changing photographic plates. Peters.

## Photo-Mechanical Notes.

### Scratchy Marks on Half-tone Negatives.

Replying to a query in "Process Work," a writer assigns the cause of this defect to the rubber solution used in edging the plate. The solution is too thick and does not dry quickly. The plate is washed while the edging is sticky, and some of the rubber is carried over the plate, to which it faithfully adheres in fine lines, and if development is prolonged these lines attract silver, and can be seen after fixing between the film and the plate. Such is my experience. When I bought Penrose's solution of rubber I was all right; but when I started to make it with naphtha and bisulphide I made it too strong, and got the 'long scratchy marks.' The usual investigation of the cleaning followed, and now I only use good methylated chloroform and a weak solution of rubber, using a clear pat only. The plate dries *instantly*, and I have not had any 'scratchy lines' since. The writer has suggested washing the camel-hair brush with warm water; this is insufficient to remove rubber, which can be done with the chloroform."

### Plating on Paper.

"Paper and Pulp" sets forth a new electric process for giving a metallic surface to paper. It consists in placing the bath in a metal tank in which are immersed two metal plates. One of the plates is formed of the metal which is used to cover the paper. A rather weak current is used for the bath. A thin layer of metal is deposited on the second plate, as is usual in the galvanostatic process. When the deposit has reached a thickness of about  $\frac{1}{160}$  inch, the plate is placed against a sheet of paper which is previously coated with the proper kind of glue. After drying, the metallic layer adheres to the paper so strongly that it remains upon the paper when it is pulled off the metal plate. A variation of the process consists in ornamenting the foundation plate with any kind of designs or letters, and these are reproduced on the metallic deposit. The solutions which are recommended in the above process are as follows:—For silver paper, a bath is made of cyanide of silver 210 parts, cyanide of potassium 13 parts, water 980 parts. For gold paper, cyanide of gold 4 parts, cyanide of potassium 18 parts, water 900 parts. For copper, sulphate of copper 18 parts, sulphuric acid 6 parts, water 40 parts.

### Natural Grain.

Husnik points out in the "Photographische Korrespondenz" that a grain screen has certain advantages over the line: the disadvantages are that the dots are of different sizes and at different distances from one another, so that the effect in the print is not even—rough and coarse. This is due to the fact that the smaller dots are actually eaten away in etching, so that blank spaces with neighbouring patches of denser dots are formed. Attention is drawn to Pretsch's process, in which silver iodide was emulsified in the bichromated gelatine. The disadvantage of this process was that the exposure was so long and the shadows were blocked up, whilst in the lights and half-tones a very coarse grain was formed. The author has now omitted the silver iodide and used only calcium chloride, which produces a grain, and states that Spitzertype is very much like Pretsch's process. In 1894 W. T. Wilkinson gave in the "Photogram," page 316, a modification of Pretsch's process, which has worked well. A solution is first made with

Cologne glue .....	50 gms.
White of two eggs .....	
Water .....	200 ccs.

The glue should be dissolved first, then the white of egg added and well stirred, and the mixture heated to boiling point to thoroughly agitate the albumen. The mixture must then be filtered and

Ammonium bichromate .....	4 gms.
Water .....	100 ccs.

Mixed, and then

Silver nitrate .....	2 gms.
Water .....	100 ccs.

Mixed with constant stirring. The mixture will be a deep red, due to the formation of silver chromate. To this should be added

enough 5 per cent. solution of calcium chloride to discharge the red colour, and then

Acetic acid .....	8 drops
Glycerine .....	10 drops

and the mixture strained and coated on ground glass which has been substratumed with silicate. A thin coating gives a fine and a thick one a coarse grain when dried at 50 deg. C. Exposure must be continued till all the details are visible at the back, and then soaked for two or three hours in a saturated solution of borax and rinsed. A cast may now be taken from this as usual. Instead of the Cologne glue a mixture of 1 part of hard to 5 of soft gelatine may be used, and the albumen and coagulation omitted. It is obvious from Wilkinson's formula that silver chloride would be formed with 'practically little or no excess of calcium chloride. If, as Husnik suggests, Spitzertype is a revival of this method, it may be worth experimenting on the above lines.

## New Books.

"Camera Work." Edited and published by Alfred Stieglitz, 1,111, Madison Avenue, New York.

Whatever criticism may be passed on the quarterly publication of which Mr. Stieglitz is the breath of life, it cannot be gainsaid that it puts before the reader American and other photography in a way more nearly equivalent to an exhibition than any publication whatever. We may differ as to what is and is not deserving of the sympathetic treatment which Mr. Stieglitz assiduously extends to all the work he reproduces in "Camera Work," but there can hardly be any discussion of the invaluable services which he renders to photography by the issue of such a quarterly. Of the volumes before us, one is a "Steichen Supplement," but the other is no less concerned with plates by the same worker and by nobody else. Our readers know, therefore, what to expect. The portrait of the late G. F. Watts, R.A., is, to our minds, the best thing. The four or five nude subjects—with never a face amongst them—have fine qualities technically: but the aim of the photographer in producing them is not clear. Since he has shrunk from admitting his models to the light of day, or of giving them anything particular to do, we must presume that they are offered as examples of beauty merely. Any anatomical charm they may have, however, barring that of proportion, is lost in the photographer's treatment of them, and a few have a shivery undressed look fatal to the highest aims of this class of work. "In Memoriam" is, by reason of its title, far-fetched in idea: it is apparently headless, and the bombshell (?) is hurtful. In its modelling, however, it is beautiful. "The Model and the Mask" makes us think of a cattle pen and a gratified prize-winner: the huddled figure is nothing if not porcine. As in these days the covers of literary ventures need have no application to the matter they protect or lure us towards, we are content to accept the cover design shown here as the best we have yet seen of photographic origin. The letterpress of these stately journals is for the most part divided between notes of the Photo-Secession and two articles by Mr. Shaw, reprinted, unadvisedly, as we think, from a London journal. Perhaps they did not read the hollow brilliancies of Mr. Shaw in America at the time, and so "Camera Work" may be excused for re-dishing them. But to English readers these fulminatory contradictions will be "cauld kail!" Mr. Stieglitz ought to be cautious, for he is playing with fire. When the risible nap has worn off Mr. Shaw's polemics his formula stands threadbare, which is "Demolish everybody and everything with all thy strength." Thus he "snorts defiance" at the kind of thing Mr. Steichen does just as much as at painters past and present. And he will be certain at some time to stumble upon an awkward truth, just as an "empty clock-case," to borrow a simile of his own, will, for one instant in twelve hours, tell the right time. In the supplement the footprints of Mr. Shaw are followed with not a little apprehension and timorousness by Mr. Maeterlinck.

The first number of "The Practical and Pictorial Photographer" (Studio series) fulfils the promises of its producers in size, variety of contents, and handsome appearance. Its literary bill-of-fare, made up from standard dishes, is doubtless none the less fitted to the amateur appetite. Among the writers, who in some instances repeat

a well-worn tale, are Chapman Jones, C. Winthrop Somerville, and J. C. Warburg. Some notes on "Light and Shade in Landscape," by Horace Munnery, is a welcome escape from conventional topics. Presumably the task of editing a photographic miscellany is less arduous than the supervision of the monographs which formed the previous "Library" series of the "Practical." We see the Rev. F. C. Lambert announced to have ready for publication a series of four sixpenny handbooks on the popular subjects of development, exposure, P.O.P., and bromide. An outlet, we presume again, for tireless energy.

## New Materials.

Artistic Film Border Negatives. Sold by the Autotype Company, 74, New Oxford Street, London, W.C.

The presentation of the photographic portrait within a border which, if suitably chosen, greatly enhances its appearance has been one of the observable fashions among photographers of standing for a year or two, yet so far as we have found it has been left to individual photographers to get prepared for themselves designs for pleasing combination printing from the portrait negative. The Autotype Company may therefore be congratulated on making good the deficiency in a way which permits of justice being done to this method of

"framing" in the print itself. The figure which we reproduce represents one (A) of the six patterns at present issued and obtainable in cabinet size (opening  $4\frac{1}{2}$  inches long) at 3s. 6d., and in whole-plate (opening  $6\frac{1}{2}$  inches long) at 5s. With each negative the necessary masks and discs are provided, and the operation of double-printing does not call for any special skill. The other patterns are equally plain and reserved in design, for the company have wisely refrained from anything like ornate decoration, a border of such character defeating the purpose for which it is intended. An illustrated circular issued by the Autotype Company gives half-tone reproductions of all six designs.

MESSRS. A. W. PENROSE AND Co. announce that they are prepared to undertake the resensitizing of commercial dry plates to order. They can bathe with any of the following dyes:—Orthochrome T

(panchromatic), Pinachrome (panchromatic high speed), Pinacyanol (red sensitive high speed), Dicyanine (extremely red sensitive), Tetra-brom-fluorescein (green sensitive), Di-iodo fluorescein (green sensitive), Homocol (green sensitive), Ethyl Red (green sensitive). These plates will be prepared as wanted, and any order received in the morning can be despatched same day. They will keep two or three weeks. The prices will be 2s. for quarter-plate, 4s. for half-plate, and 8s. for whole plate. Special filters can be supplied to suit the colour sensitiveness of either of the above plates, combined with the highest transparency, to allow of the shortest possible exposures, especially for trichromatic portrait work and landscape photography, or reproductions of oil paintings in badly lighted galleries. Approximate ratios will be given with each set of filters for daylight or open arc. If required, a ratio of 1:2:2 can be obtained by proper combination of plates and filters. The bathed plates will be prepared under the immediate supervision of Mr. H. O. Klein.

## CATALOGUES AND TRADE NOTICES.

The London Stereoscopic Company are holding, at 54, Cheapside, a large sale of photographic apparatus and materials, which should repay a visit by both amateur and professional photographers. We see from the 32-page list of the lots that very considerable reductions are made on the list prices, and the opportunity—which can be embraced by post—appears to be one for picking up cheaply a good hand camera, lens, or enlarger.

Messrs. Elliott and Sons, Ltd., send us a set of show cards and specimens, a parcel of which they will be pleased to send any dealer on application. The present series is even more attractive than previous issues of the kind, which is saying a good deal, for Messrs. Elliott's judgment in matters of window display has impressed us of late years as altogether admirable.

A NEW list of "Amateur Photographic Requisites" has been issued by the London Stereoscopic Company, 106-108, Regent Street, W., and though not professing to be an encyclopædia of everything photographic, includes a selection of high-class cameras and accessories which can be specially recommended. The Company offer a copy free to every applicant, and are prepared to advise on the choice of apparatus personally or by post.

## FORTHCOMING EXHIBITIONS.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 16-21.—Redcar Photographic Society. Entries close April 9. Secretaries, W. H. Taylor, Esplanade, and J. M. B. James, 4, Elton Street, Redcar.

April 18 to 21.—Bolton Amateur Photographic Society. Secretary, T. W. Cross, 27, Latham Street, Bolton.

April 20-21, 1906.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.

April 27-May 27.—Northern Exhibition (Manchester). Sec. G. M. Morris, 9, Chandos Road, Chilton-cum-Hardy, Manchester.

May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

May 15 to 17, Clevedon Photographic Society. Last day for entries May 9. Secretary, Rev. E. H. Sandford, 18, Hallam Road, Clevedon.

A FIRE took place recently on the premises of Messrs. G. W. Wilson and Company, photographers, St. Swithin Street, Aberdeen. About five o'clock an employe noticed that something was burning in the collotype department, and on investigation he found that a bench was on fire, having apparently become ignited by a gas ring on the floor, which had inadvertently been left burning. By the time the brigade put in an appearance the fire was almost extinguished. The damage amounts to a few pounds, and is covered by insurance.

CAMERAS Barred.—The Japanese worship "Katori" was open for inspection at Birkenhead last week, and was visited by about 6,000 persons, the proceeds going to local charities. The Japanese sailors received the visitors with great courtesy, although cameras were strictly prohibited.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

rl.	Name of Society.	Subject.
.....	Aberdeen Amat. Photo. Assn.	President's Prize, Competitive Prints—any subject.

.....	Cardiff Windsor Amat. Ph. Soc	Lantern Slides. Mr. H. T. Malby.
.....		Self-Toning Aristo Paper.

**FULL PHOTOGRAPHIC SOCIETY.**—At the annual meeting, held on Tuesday, April 5, the following officers were elected for 1906-7:—President: Rev. C. O. Stewart, M.A.; Vice-presidents: G. F. Stow, jun., and A. E. Hindson; Treasurer: D. L. Cockcroft; a Solicitor: R. E. Johnson; Hon. Editor: W. Gilleard, 18, Grey Street, Hull; Curator Enlarging: J. T. Dyson; Hon. Secretaries: Garnet Galtry, 146, Spring Bank, Hull, and Chas. Davis; mail: Messrs. R. Clark, W. L. Willatt, W. Dalton, W. H. Irish, and L. Stephenson.

**WATFORD CAMERA CLUB.**—An exhibition of prints executed on the Croft Pigment Paper was held at the headquarters on Thursday, April 5. Mr. Page Croft also sent some prints for development. There was a fairly good attendance of members and others, and all were much struck with the simplicity of manipulation and ease of control.

**WIDYON CAMERA CLUB.**—The President, Mr. W. H. Smith, brought the new Ilford "Amauto" plate to the attention of the members last week, an innovation he regarded as ideal for lazy workers. So far as his brief acquaintanceship with the newcomer went, it appeared to be fast, clean working, and possessed a good deal of gradation, with latitude. Several plates were developed in a plain solution of carbonate of soda, and good negatives resulted in each case. Mr. Mees supplemented Mr. Smith's observations by pointing out that apparently an "Amauto" plate could be over-developed. The merits of Messrs. Edmunds' Cubrome were next illustrated by several bromide prints and lantern slides—the work of members—being passed round for inspection. These were toned a capital warm sepia, and then producers testified to the ease of working Messrs. Edmunds' product, and the certainty with which good tones could be secured. Unless care was taken there was, however, a tendency to obtain perhaps too warm a tone, hardly suitable for some subjects, though appropriate for others. In this connection it was mentioned that the developer had had an important bearing on the final colour. In one respect Cubrome toner failed to come up to the mark, the familiar "egg" odour being but slightly in evidence. Towards the end of the evening the President handed round a set of prints,

in black and varying shades of warm brown to cold sepia, and said he should be glad to know what those present thought of them, and if they would tell him what the process was. There was an unanimous expression of opinion that, judged from the standpoint of colour, shadow transparency, richness and depth of image, they were the finest prints ever shown in the club rooms, but all failed to identify the process itself. It came as a complete surprise when Mr. Smith revealed the fact that they were forerunners of a new "Platinotype" paper shortly to be placed upon the market. No further information was forthcoming, but doubtless fuller particulars would be obtainable at the offices of the Company.

## News and Notes.

**SIR WILLIAM CROOKES**, the eminent scientist, celebrated his golden wedding last week. Since Sir William, who will be seventy-four in June, entered the College of Chemistry in 1848, many marvels of science, some of which he helped to perfect, have been wrought. Londoners in particular owe him a debt of gratitude for investigations into sanitary matters and the world in general for the Crookes' tube. The following are a few of the principal "milestones" in the scientist's career:—Gained the Ashburton Scholarship, 1849; gold medal and prize of 3,000 fr., French Academy, 1880; President British Association, 1898; Albert Medal, Society of Arts, 1899; discoverer of thallium, a new element, 1861; the radiometer, 1875; the spintharoscope, 1903. Sir William Crookes, as most of our readers probably know, was one of the earliest amateur photographers, and eagerly experimented with the camera as far back as 1855. According to the "Daily Chronicle," the excellent photograph of Lady Crookes, which was reproduced on the invitation cards to the golden wedding party on Tuesday, was taken in the year mentioned by Sir William himself, and forms a most interesting reproduction of the fashion of the time. We see how nice some people used to look in ringlets! Sir William was an enthusiastic amateur photographer, and was always saying to his wife, "Sit!" And she used to reply, "It sounds like a hen."

**THE YORKSHIRE UNION.**—Speaking at the annual meeting of the Yorkshire Photographic Union, in Batley, Mr. Atkinson, of Hull, the new president, said he believed that the Union had, and would continue to have in the future, an influence in the cultivation of taste which would in time permeate all classes of the community. It was not necessary to be artistic in order to be utilitarian. Speaking of photography as an art, Mr. Atkinson pointed out that photography would soon lose its fascination for many of those who took it up were there not in it something beyond the mere accurate production of any scene or object. Photography was an excellent medium for artistic expression, and it was also an excellent educational medium. The Mayor of Batley (Alderman George Hirst, J.P.), accompanied by the Town Clerk (Mr. J. H. Craik), welcomed the delegates, and thanked them for the honour they had conferred upon the town by holding their annual meeting there.

At Albury, a building occupied by Mr. A. Pustela, as a photographic studio, has been destroyed by fire, together with the contents.

**COBURN** at the "Cheshire Cheese."—To Mr. Alvin Langdon Coburn, as a member of the photogravure class at the Bolt Court School, is due, we believe, the idea of a students' supper, which duly took place on Tuesday of last week in the ancient tavern which stands within a stone's throw of the L.C.C. School. The circular of invitation or notification is quaintly worded:—"Ye feast of ye photogravure devils from ye ancient Bolt Court. Held on ye tenth day of ye fourth month, at ye 'Old Cheshire Cheese,' in ye yeare

MCMVI.

Ye fare will consist of ye renowned pudding, steaming hot, and ye far-famed cheese. Also those who so desire may quaff of ye foaming ale."

A **NEGATIVE** which has strong high lights and thin shadows requires the use of a local reducer to make a satisfactory printing negative. If the high lights are not too dense, writes the "Photo-Era," the plate may be immersed in a solution of ammonia persulphate—a reducer which has the quality of first attacking the

high lights before beginning to affect the shadows or thin part of the negative. To use, dissolve 2oz. of the salts in 10oz. of water. The reduction begins very slowly; but as soon as the chemical begins to act it works very rapidly, so that it is necessary to watch the process closely to prevent over-reduction. As soon as the dense parts are sufficiently reduced, rinse the plate and place in a bath made of a 10 per cent. solution of sulphite of soda. Let it remain in this bath five minutes, wash well, and dry. The sulphite of soda converts the persulphate into sulphate, which has no effect on the plate. If the ammonia persulphate is not entirely eliminated from the plate it will in time destroy the negative.

In the photographic competition organised by "The British and Colonial Druggist," in connection with the Chemists' Exhibition and open to all chemists and their assistants, no less than five of the awards, including the first prizes in both sections, were obtained by members of the staff of Burroughs, Wellcome and Co., whose pictures were produced with "tabloid" photographic chemicals. The premier award was won by a member of Burroughs, Wellcome and Co.'s staff for the fourth year in succession.

**A PHOTOGRAPHIC FATALITY.**—At Highcliffe, seven miles from Bournemouth, Miss Florence Leach, age 33, was killed by the falling of the cliffs whilst she was being photographed in a group on Friday. The party consisted of six persons, most of whom are employed at Bournemouth post office. According to the evidence given at the inquest on Saturday last by Mr. Pulsford, the party walked along the top of the cliffs at Mudeford for about 200 yards, and then went down to the beach. There they were grouped by witness, deceased standing behind the other four ladies, and close up to the cliffs. Whilst fixing the camera witness heard a rumbling noise, and as far as he remembered he uttered a cry of warning. A quantity of cliff fell, covering deceased. The other four rushed into the sea to a depth of four or five feet in order to escape the debris. Mr. Pulsford tried to remove the fallen boulders, but another fall took place, and it was not until assistance came that the body of Miss Leach was recovered. A verdict of "Accidental death" was returned.

**MANUFACTURE OF Plate Glass.**—A consular report from Nuremberg recently issued gives details of a new invention in the glass-plate industry, which, if it does all that is claimed for it, will seriously affect the blowing glass-plate industry. Hitherto, writes a correspondent of the "Birmingham Post," two methods have been employed in the manufacture of crystal plate-glass and mirror and window-glass—namely, that of casting and blowing. The new method is the invention of Mr. Fourcault, a Belgian, who has sold his patent to a European syndicate of plate-glass manufacturers for 952,000 dollars. This syndicate consists of German, French, and Belgian manufacturers, and one Bohemian factory. Up to the present in the making of window-glass the molten substance has been blown into cylinders by glass-makers' pipes, and subsequently flattened, while in the making of plate-glass the viscid mass was cast from the pots and rolled. The new invention draws the molten substance from the pot, and conducts it between rollers lying side by side. Seventeen pairs of these rollers are built up tower-like above the pot. The liquid mass cools on its way between the rows of rollers and comes out from them polished on both sides, in any desired thickness, beautifully flattened and ready for use. At present dimensions of from 157.48in. to 39.37in. can be made, but experiments are being conducted to allow of the manufacture of from 98.42in. to 68.90in. as well. It is believed that this invention will bring about a revolution in the trade. One early result would be that the manufacturing of plate-glass of 157.48in. and less would undergo an entire change, as the making of glass-plates would come chiefly within the scope of the plate-glass furnaces. Splendid as this invention appears, it may greatly injure the plate-glass industry in the Bavarian city of Fuerth, as it would be impossible for the glass blower to compete with a simple and cheap process of drawing out the glass mechanically.

MR. FRANK R. FRAPRIE, formerly associate editor of the "Photo-Era," has joined the staff of the American Photographic Publishing Company, and will conduct the "American Amateur Photographer."

**ROYAL PHOTOGRAPHIC SOCIETY.**—On Tuesday next, April 24, two papers are to be read, one on "The Red-sensitiveness of Dyed Films," by W. A. Scoble, A.R.C., Sc., B.Sc., and another on "A Natural-colour P.O.P. and the Smith Three-colour Plate," by Dr. J. H. Smith, of Zürich.

## Commercial & Legal Intelligence.

**THE Coupon System.**—At the Bristol Police Court, on April 11, Frederick Arthur Webb was charged with stealing 19s. 6d., the money of Agnes Bullock, a servant, at 33, Cornwallis Crescent, Clifton. The defendant is a photographer in the employ of Mr. Moore, Park Street, and it appeared he called on the complainant and asked her to purchase a coupon for her portrait. She agreed to give 6d. for the coupon, but had only a sovereign, which was given to her for wages. The defendant stated that he would get change if she would take charge of a case which he had, and she gave her a receipt for the 6d. He did not, however, return, and ultimately the matter was put into the hands of the police. The defendant was apprehended in York Road, Bedminster. In his defence he stated that he was willing to repay the money, but when apprehended it appeared he had only 4d. in his possession. Mr. Moore attended before the magistrates, and in answer to them he said he received an excellent reference with the defendant from his former employer. The advantage to the girl upon taking a coupon was that she would get a portrait for less than the usual price. The brother-in-law of the defendant offered to repay the complainant 19s. 6d., and after consultation the magistrates allowed the defendant to go upon payment of 25s., his brother-in-law being security for his good behaviour for six months.

**A CARDIFF CANVASSING CASE.**—At the Cardiff Quarter Sessions, on Thursday in last week, Edward Kelsey was indicted for obtaining 14s. from Mr. Clement Stone under false pretences. The case, on its hearing in the Cardiff Police Court, was fully reported in our last issue. According to the prosecution, Kelsey visited different places during the week, and on the Saturday handed in the orders he had obtained, when he was paid a deposit of 1s. in respect of each order. Inquiries were then made by Mr. Stone, and if the orders were found to be genuine the defendant was paid 3s. 6d. for each. On February 24 the prisoner handed four small photographs to Mr. Stone, and said the owners of them required enlargements. He asked to be paid the 3s. 6d. commission in respect of each order that day, as his wife was lying ill at home and he wanted the money. Learned counsel alleged that the four orders for which Kelsey was paid were bogus ones. The prosecutor stated that the orders were supposed to have been obtained at Treorky. When a canvasser was sent to verify them it was found that they were bogus. The prosecutor was cross-examined at length by the defendant. Witness admitted that he had not received any fictitious orders previously. The prisoner, in evidence, said he went to Treorky and called at the "Red Cow" public house. He there saw four men, who gave him the orders. He entered up the customers' names and addresses after leaving the public house, and although the number of the house which he gave might be wrong, he believed the men existed. The jury found the prisoner guilty, and the Recorder passed sentence of two months imprisonment.

**THEFT from Messrs. Southall Bros.**—At the Birmingham Police Court last week, Harry Cubbin, 117, Branstons Street, was charged with stealing a Kodak camera and stand from his masters, Messrs. Southall Bros. and Barclay, of Broad Street. He pleaded guilty. Mr. Willison pleaded for leniency for the prisoner, who, he stated, had been led to commit the theft through financial difficulties. Prisoner was sent to gaol for six weeks' hard labour.

**A TRAVELLING Photographer's Record.**—At the Leeds Quarter Sessions, on Monday, William Burton pleaded guilty to stealing sixty-six yards of flannelette, the property of Edward Chandler, on March 26. The Recorder remarked that the prisoner had not confined his operations to one part of the country, and proceeded to read off a long list of names of places where Burton had been convicted. The prisoner: I am a travelling photographer, and my business takes me all over the country. The Recorder said Burton seemed to have levied toll at all these places. He had taken bicycles, bags, boots, shawls, rugs, stockings, and other articles. The prisoner was sentenced to twelve months' imprisonment with hard labour.

## Correspondence.

*Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*We do not undertake responsibility for the opinions expressed by our correspondents.*

### MEASURING SHUTTER SPEEDS.

To the Editors.

Gentlemen,—I see, in printing my letter of the 3rd inst., in your issue of April 6, there is a compositor's error which, as it alters an important factor in a formula, I hope you will allow me to correct.

It is in the sentence where I explain how the constant  $\frac{2}{\pi}$  in my formula makes the necessary correction for the harmonic motion of a pendulum. The sentence should read:—"It is based on the fact that in such a motion the velocity in the middle of the swing is equal to  $\pi$  times (not eleven times, as printed) the length of the g, divided by the periodic time."—Yours faithfully,

ARTHUR A. WATKINS.

14 Lodge, Vanbrugh Park, Blackheath.

April 9, 1906.

The above letter was unfortunately received too late for insertion in last week's issue.—Eds. B.J.P.]

### THE INVENTION OF SELF-TONING PAPER.

To the Editors.

Gentlemen, If you will kindly allow me the space, I wish to ask you to exercise the fairness and impartiality for which you are noted in determining the justice of the claim I make to being the inventor of the practical method of incorporating the toning salts in the coating of photographic papers, and doing the toning chemically, appertaining to papers known as "self-toning."

My experiments were conducted as far back as 1868, when I was then a youth and an employee, and I commenced using the process, practically, in my own business for plain salted papers in 1870, and it was for that kind of paper, which was known to my employees as the exact formula, until the time that the platinum process replaced the plain salted papers. I published my method in 1888 in "Wilson's Photographic Mosaics" under the heading "The Uses of Chloride of Gold." The reason I delayed the publication so long was that I was constantly experimenting with an attempt to apply it to albumenised papers, in order to make something of it commercially, as they were almost exclusively used in the profession at that time, not considering its application to plain prints of sufficient value. Chemists will, of course, understand I failed, as any attempt to make a mixture of the auric chloride with albumen must fail.

It may, of course, be possible that some have preceded me in this matter, which has now become a very important method of photographic printing, and if you find it so, the truth will do no harm; at some time, if I am entitled to the credit of the method, it should be in fairness to be given to me.

What makes me think that my claim has some foundation in fact is that a patent was taken out in 1891 covering the self-toning principle, and a self-toning collodion emulsion paper was manufactured under that patent and exploited by a gentleman of the name of M. Wille at Newark, N.Y., in 1892. Shortly after the American Aristotype Company commenced the manufacture of a similar paper, and were sued by the M. Wille concern for infringement.

I was called on by Mr. J. J. Kennedy, the counsel for the defendants, to find evidence of the invalidity of the patent, they having heard that I had made publication of the essential principle involved. It took some time to remember and hunt up the publication I had made (as heretofore mentioned), though I knew the patent could not be sustained under our laws. The suit was abandoned. I learned that the Eastman people bought out what was left of the concern and afterward continued the manufacture and sale

of the self-toning paper. One thing is certain, there is no valid patent on the process, and the action herein noted lends colour to the view that my publication was the first of any practical method of so-called "self-toning."

The reason I send this communication to you, Gentlemen, is that your publication appears to be the most thoroughly posted on the history of photography, and of your well-known love of fair play in such matters. I mentioned the subject one time to Mr. J. Traill Taylor when in this country, and he seemed to be under the impression that I was the originator, though he had a vague idea that a suggestion of such a method had been made in publications back in the fifties.—Very respectfully yours,

D. BACHRACH.

Baltimore, March 31, 1906.

[We will refer to our correspondent's letter in a forthcoming issue.—Eds. B.J.P.]

### A COPYRIGHT CASE.

To the Editors.

Gentlemen,—We recently took proceedings against the publisher of a book called "Paton's Lists of Schools and Tutors" to put a stop to the reproduction in such book of a number of photographs taken by us, at our own risk and expense, of certain schools advertised in the book.

The action came on for trial on the 4th inst. before Mr. Justice Farwell, and was decided against us on the grounds, as we understand it, that permission, given to us by the proprietors of the schools, to take photographs of the exterior and interior of the school, was a good consideration under the Act, and was sufficient to divest us (although we were expressly held by Mr. Justice Farwell to be the authors) of the copyright of the said photographs and vest same in the school proprietors. It seems to us, and we may say that our counsel pointed this out to us, that the effect of this decision is to prevent the copyright of any photographs whatsoever, except possibly "surprise photographs," remaining in the photographers or author. We think this is a most alarming proposition, and one of great importance, not only to ourselves, but the trade at large, and that, therefore, steps should be taken with a view to get the decision, if possible, set aside.

If any photographers or publishers who may read this letter are of the same opinion, and feel inclined to give their support to an appeal, we should be pleased to hear from them.—Yours faithfully,

The Photographic Tourists' Association, Carl Stackemann, Manager.

[We refer to this letter under "Ex Cathedra."—Eds. B.J.P.]

THE Historical Medical Exhibition, to be arranged in London shortly by Mr. Henry S. Wellcome, has already been mentioned in our columns. Mr. Wellcome has now issued a pamphlet inviting contributions to the exhibition, the character of which, we may say, will be strictly professional. One section of the exhibition will deal with photography from the historical point of view, the exhibits to be classified as follows:—

- (a) Objects illustrating the invention and history of photography.
- (b) Early cameras and apparatus.
- (c) Daguerreotypes.
- (d) Portraits of the pioneers of photography.
- (e) Original papers and early MSS. on photography.
- (f) Application of photography to medicine.
- (g) Early X-ray apparatus.
- (h) Curiosities of photography.

Mr. Wellcome will be glad to hear from any collectors who are able to participate in the exhibition, and communications should be addressed to him at Snow Hill Buildings, London, E.C.

THE latest addition to the list of the general papers which provide photographic reading for their subscribers is our bright and varied contemporary "The Onlooker." The "Photographic Notes," which commence in to-morrow's issue, are illustrated by half-tones well made and printed, a feature of the "Onlooker's" columns which we are informed is to be maintained.

## Answers to Correspondents.

- \* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- W. Rochard, Honey Street, Bodmin, Cornwall. *Photograph of the A.F.C. 190 1906 Bodmin Football Team.*
- W. J. Reed, 2, Marina Arcade, Bexhill, Sussex. *Photograph of the First Trampcar from Bexhill to St. Leonards-on-Sea.*
- A. Osborne, 87, High Street, Hadleigh, Suffolk. *Photograph of Acton Church Suffolk. Photograph of Catherine Foster's Cottage, Acton, Suffolk.*
- G. Cross, 173, Lord Street, Southport. *Photograph of "Hoprend," Winner of the Waterloo Cup, 1906.*

**CHARGES FOR NEGATIVES.**—Will you kindly answer the following query in your columns? I have been requested to quote for a price for taking P.P.C. negatives, that is, half-plates, at different places in the country. Could you tell me what is a fair rate for quoting for a dozen such negatives so as to cover all initial cost, besides allowing for a fair margin for travelling, etc. I do not know what I ought to quote, but I thought about 25s. per dozen, at the rate of 2s. 6d. each negative. Thanking you in anticipation.—C. R. DODD.

How is it possible for us to say? We do not know anything of your capabilities as a photographer. We have no idea where the "different places in the country" are, how far they are apart, or the cost of travelling to and from them. Neither do we know the value you put upon your time, which, by the way, we imagine is very little from the prices you mention. Surely you can estimate what will remunerate you for your work better than anyone else can.

**AN ASSISTANT'S QUERY.**—If I accept an engagement (situation) for a permanency, should I be subject to be discharged after twelve months by a short notice?—X. Y. Z.

Certainly, unless you make a legal contract. So long as you fulfil the terms of such a contract you are not liable to discharge without compensation.

**UNDERGROUND PHOTOGRAPHY.**—I have to take photographs of machinery in a coal mine, and shall be unable to use a flash of any sort, owing to the danger of an explosion. The mine is lighted by electric incandescent lamps. But I understand these are of no practical use for photography. Could you inform me what electric lamp would suit my purpose (it must be in an air-tight globe), and what you would think the exposure would be. I thought of having an arc lamp fitted with an air-tight globe.—ERNEST CARVER.

We should say the arc light is the only one you can use, although it is far from suitable for the work. You should provide as much reflected light as possible by means of white screens, and give an ample exposure. With rapid plates (backed, of course) and about *f*/16 stop the exposures would run into several minutes.

**TITLES ON POSTCARD NEGATIVES.**—1. How to title negatives for postcard printing (reversed lettering on direct negatives) so that title prints white on dark ground; also to so title them that name is dark on white ground (as — cards, for instance, are done). I can very effectively name negatives by hand, but the difficulty is to do so, neatly, reversed. I have purchased reversed rubber type, but it proves quite useless for some reason. 2. A Scotch firm is supplying envelope sheaths of excellent make to carry glass half-plates. I have seen them, but

mislead name of firm (a Glasgow one, I believe). Can you help me in this?—ENQUIRER.

The titles are in the first place photographed down from hand or typographical lettering, and a negative or positive made on a gelatine plate according as black letters on a white ground or the reverse is wanted. It is usual to photograph a number at a time. The various titles are then stripped off on to the negative, a portion of the film of the required size being cut from the latter if it is necessary. 2. You probably refer to the Mackenzie-Wishart, 17, Douglas Street, Glasgow.

**BOOK ON STUDIO.**—I should be obliged if you could suggest a book on how to manage a studio. I am just taking a studio over, and have not a great experience of the system required, and have thought that perhaps a book on the subject would be a great help.—W. H. J.

"The Photographic Studio," by Bolas (2s.); and "The Studio and What to Do in It," by H. P. Robinson (2s. 6d.). Any photographic dealer or bookseller will supply you with these works.

"NERO."—O. Flammger, Dept. C., 39, Redcross Street, London, E.C.

**VARIOUS.**—1. What are the advantages of using pyro in crystals instead of powder? Does it work different? 2. My studio is 16 ft. long by 10 ft. wide. I want a cabinet portrait lens to give a full-length figure on cabinets, also for groups same size. What focus lens do I require, distance between camera and sitter not to exceed 12 ft., to allow for working space for operator? 3. Have you any objections to using self-toning paper for professional work? 4. Can you recommend a good print washer for 1-1 plate work and under? Not a rotary washer, as I find that prints 1-1 plate size kink when placed in the rotary washers. I have had some trouble with this matter.—OPERATOR.

1. No pyro dust in the dark room, and greater convenience in weighing out. The action of the developer is the same in each case. 2. For the full-length figure on the cabinet you require a lens of about 11½ in. focus. 3. Your question cannot be answered in regard to self-toning papers as a class. The debateable points in regard to self-toning papers are the methods of working them. If the conditions are such as to set up sulphur toning, we cannot anticipate great permanence in the results. 4. A good washer for large prints has still to be made. Separate hand washing is the best method you can use.

**B. R. J.**—In our next.

**TONING BROMIDES.**—I should be much obliged if you would kindly help me by replying to the undermentioned query in the current week's issue. I have just tried the sulphide toning for bromide papers recommended on p. 978 of the "Almanac." I printed very deeply—as the first print I tried, which was only an average print, remained bleached after being in the sulphide bath fifteen minutes—but after bleaching and being in the sulphide bath for quite fifteen minutes again the image failed to come up. Could you explain what is the matter, as I spoiled quite a batch of prints experimenting?—R. D.

We can only say that in our experience the formula answers perfectly, and that it is very little different from others in daily use. We suggest that you have been supplied with sulphite instead of sulphide.

**ANACHROMATIC.**—We are not aware that the firm has offered to send specimens. We have not any.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Mr. F. C. Tilney contributes an appreciation of the photographs Dührkoop now being exhibited at the BRITISH JOURNAL, characterising them as fresh, sound, and preserving the virility and intensity of the sitters. A portrait of Herr Dührkoop by Strauss, St. Louis, appears on page 325, and a reproduction of one of indoor portrait studies in the Exhibition is presented as a complement.

At a conference of the Professional Photographers' Society of New York, the President, Dudley Hoyt, proposed a scheme of joint organisation for photographers throughout New York State. Mr. MacDonald succeeds Mr. Hoyt as President of the P.P.S. of N.Y. (P. 328.)

Mr. A. L. Coburn is showing a collection of his photographs in Liverpool for two weeks, commencing May 1. (P. 337.)

The Professional Photographers' Association contemplate a "single picture" exhibition on the lines of the recent one in America, and to be held at the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY. (P. 337.)

The properties of half-tone engraved plates as regards depth are the subject of some lengthy recorded experiments by Mr. N. S. Amstutz. (P. 331.)

Some historical notes on self-toning paper show that the claim Mr. H. Bachrach to have invented it in 1888 may be conceded as far as the published literature of the subject goes. A very similar formula to Mr. Bachrach's appeared in 1864, but without any claims to a self-toning method. (P. 323.)

Two deaths from ammonia occurred last week. Some precautions in the use of the strong liquor ammonia .880 are mentioned on page 323.

Norwich lady photographers combined last week in the cause of art, holding a sale exhibition of their work. (P. 322.)

At the London and Provincial last week the new "Matos" papers are accorded a very favourable reception on the occasion of their demonstration by Mr. L. Thornton. (P. 338.)

A remarkable exhibition of multiple-gum prints in colours is now being held in Hamburg. The collection includes the work of the Hofmeister brothers in this new field. (Pp. 321 and 334.)

## EX CATHEDRA.

**The Hamburg School of Pictorial Photography.** For the past fortnight an exhibition has been held, in the Hamburg Art Gallery, of pictorial photography. It forms the eleventh of the series of exhibitions organised by the Hamburg Society for the Promotion of Amateur Photography commenced in 1893. In previous years the Society's exhibitions have possessed an international character from the inclusion of foreign work, but on the present occasion, which marks an interregnum of three years during which no exhibition has been held, it has been thought well to limit the work to that of members of the Society and other photographers in Hamburg. And the result quite justifies this policy of self-reliance. There is in Hamburg a small body of workers of whom little has been heard for some years past. Oscar and Theodor Hofmeister, H. W. Müller, Bernhard Troch, and Dr. Ed. Arning form a body of workers whose aims at pictorial expression in photography have been sought through the medium of the gum-bichromate process, but in a manner which entirely marks them out from those of other exponents of that process. In Hamburg they are multiple gum-

mists, and their experience of the technique of the process has led them to produce pictures of very large size, so that, in the matter of space alone, one or two prints by the Hofmeisters would somewhat embarrass a hanging committee. The character of the Hofmeisters' work—we may refer to the two brothers as the leaders of the Hamburgers—is such as demands a setting of its own in an exhibition, for it is big with a bigness which is not size merely but an embodiment of nervous and imaginative force. We confess to not understanding some of their work, and we admit our inability to appreciate the motives which have prompted them in not a few instances, but we would hasten to add that by no other photographer have we seen compositions which so convinced the observer that here were pictures which showed commonplace scenes and themes through the temperament of the artist. In the earlier work especially of the Hofmeisters, the imaginative treatment is to be seen. All of it has been done in gum, and almost all in multi-gum, but we will anticipate the cry of fake which is easily raised by saying that a number of direct P.O.P. prints from the original negatives which Herren Hofmeister showed us when on a recent visit to them, possessed almost precisely the character of the large gum-bichromate prints. In fact it was evident that by their assiduous and infinite patience, care in the selection of a view point, and their thorough use of screens and plates which will give them their impression of the scene, that the Hofmeisters seek to get all their effect in the negative with greater pains than the average worker who proposes to print in platinum-type or carbon. Of late they have taken up gum in multi-colour, and their results and those of their friend Müller

are an eloquent testimony to the possibilities of the process in the hands of the artistic and perfectly practised worker. One must pay a tribute also in judging their work to the truly Teutonic persistence with which perhaps twelve different printings are done for a single picture. Yet many of the finished results which we have seen and which are now being exhibited at Hamburg are perfectly harmonious in their colouring, and an immense advance on the gaudy multi-colour gums which were shown at the Royal Photographic Society's Exhibition some three years ago.

\* \* \*

#### Machine-engraved Half-tones.

The "acrotomes" mentioned in the lengthy article by Mr. Amstutz, which we reprint with the original illustrations in this issue, may raise a query from those who have not followed Mr. Amstutz's invention of a machine for the mechanical engraving of half-tone blocks. The "acrotome," as the machine is called, is in essential a rotating cylinder to which a fine graving tool can be approached with micrometric accuracy, the graving tool also making a certain (and adjustable) step from left to right for each revolution of the cylinder. A negative carbon relief (i.e., printed from a positive transparency) on celluloid is laid round the cylinder, relief side outwards, a piece of plain celluloid strapped to it, and the cutting tool then adjusted to the celluloid surface. On the revolution of the cylinder the step-by-step movements of the cutter engrave the celluloid in lines corresponding in thickness to the relief of the carbon print, and thus reproducing the light and shade of the original print. From this "acrotome" a stereo or electro is taken for the printer. Those anxious to study this method of "top engraving," as it has been called, may consult "The Process Photogram," June, 1899, April, 1900, June and November, 1903, where details of the machine and the methods of using it have appeared.

#### Photographing the Dead—A Coroner's Remarks.

At an inquest held last week on the body of a woman who died from poison at a Pimlico hotel, and whose identity has not yet been discovered, the coroner made some strong remarks on the system under which bodies in this country were photographed as compared with that of France. He said that coroners had no power here to order a body to be photographed at once, and the result of photographing after the lapse of several days was never satisfactory; and he could quite conceive that in this case relatives would be completely puzzled if asked to identify the body from the photograph. It represented something that hardly looked like a human being at all. He added that the photographs of dead persons were not taken in an intelligent way. They ought to show the shape of the head and the appearance of the person in life, so far as that appearance could be reconstituted after death. The present plan, however, was to take only the photograph of the head while the body lay in a recumbent position. Judging from the several photographs of such subjects as we have seen we should say that the coroner's strictures were well grounded, for the photographs were not taken in an intelligent way, or by a skilled photographer who understood his work or what was actually required, namely, a means of identification. Sometimes the work is done by an amateur, a policeman, or perhaps a third or fourth rate professional living close at hand. He is simply told to take a photograph of the body; and he takes it. But if a skilled artist were employed he would appreciate the object of the photograph, and the result would, in most cases, be quite different. It would be a good thing if the coroner in each district had the power to appoint a good class artist as his "official

photographer," to take photographs when called upon to do so, and sometimes the places, and their surroundings, where the bodies were found. He might also have the power to order the photograph to be taken promptly.

#### Altruistic Photography.

A bright example which might be followed by societies governed by selfish men has been set by the Norwich Ladies' Camera Club, the members of which have just held an exhibition of their photographic work in aid of the Jenny Lind Infirmary for Children. Some two hundred photographs were brought together—"under distinguished patronage," as the county newspapers are in the habit of saying—and were offered for sale on behalf of the local charity. Such an exhibition, planned purely in the interests of philanthropy, is something new, if we are not mistaken, in photographic society circles, and the ladies of Norwich have our sincere congratulations on their enterprise, the fruits of which, we hope, are satisfactory from a financial point of view. Photography alone, so we read in a newspaper report, was not the only incentive to visit the exhibits, but shared this duty with a concert and a theatrical performance, in the production of which some few fortunate men of Norwich were allowed to participate.

\* \* \*

#### Photography of the Infra Red Spectrum.

The paper read before the R.P.S. on Tuesday last, whilst dealing with the red sensitiveness of dyed films, may be useful to those who wish to take up the spectroscopic study of the infra red, a region of the spectrum which has but little interest for the practical photographer, except that therein lies the greatest heating effect of sunlight. A curious omission from the author's paper will be at once recalled by all conversant with the subject, and that is the absence of any reference to the classic work of Sir William Abney on the infra red, which was reported in our volume for 1880. The method then adopted was a peculiar collodion emulsion which absorbed the red rays and transmitted blue, and with this Abney recorded up to wave length 20,000, and stated by a modification of the formula it was possible to record the radiations from a kettle of boiling water. Possibly the use of this collodion was excluded in the present case by the fact that a celluloid film was used, and the visible part of the spectrum was also required, for which this emulsion is useless. The author comes to the conclusion that pinacyanol is the most satisfactory dye up to wave length 7,000, and beyond this alizarine blue S would have to be used. In the "Archiv für Wissenschaftliche Photographie" for 1900 Lehmann suggested the use of a mixture of alizarine blue S with nigrosine W.S. plus ammonia and silver nitrate, and was able with this to photograph up to wave length 10,000. Another dye, which has been used by Eder and Valentia, is Columbia Green, with which they have obtained sharp results up to wave length 8,660. The most valuable work on the infra red has, of course, been done by the late S. P. Langley with his bolometer, a delicate thermopile which will record a variation in temperature amounting to one-hundred-thousandth of a Fahrenheit degree. This instrument was combined with a mirror galvanometer, and the reflections of the latter photographically recorded.

\* \* \*

#### "Camera Craft."

We can hardly let the occasion of the destruction of San Francisco pass without a sympathetic reference to our contemporary which is produced and printed in the Western capital. It is difficult to expect that amid the almost total annihilation of the city the offices of our contemporary in Market Street have escaped scathless. By a coincidence one article in

a "Camera Craft" for March, which reached us a few days ago, is devoted to "Photography on a Burning Land," the experiences of a photographer on the volcanic Whakari off the New Zealand coast. The terrors of this active volcano, whereon no living thing, bird or insect, can exist, are probably feeble in comparison with those which burst suddenly upon San Francisco. We hope it will not be long before we hear that Editor Fayette J. Mute and his confrere, Dr. D'Arcy Power—the latter known to many photographers here from his visits to Europe—are in safety, and engaged in making good the continuity of their publication.

**Baths from ammonia.** It is not everyone who uses liquor ammonia in photography that is aware of the danger that may lurk in places where it is stored, even when in small quantities. Last week an inquest was held at Hammersmith on the bodies of two men, employed at Cadby Hall, on Good Friday. According to the evidence, as reported in the daily papers, the accident was due to the closing of a valve of the machinery in the motor room, which caused the ammonia to escape, death in both cases being due to internal injuries set up by ammonia vapour. A verdict of accidental death was returned. The liquor ammonia of commerce, known generally as .880, is really a dangerous thing to keep in a small dark-room, for the bottle containing it should happen to get broken, and escape into the room, unless they immediately make their escape into the open air, might sustain serious injury. Liquor ammonia is a solution of ammoniacal gas in water. That having a strength of .880 is a nearly saturated solution, and if it be kept in a warm place the gas expands and tries to escape, with the result, as most are aware, that the top of the bottle is frequently blown out, the gas escapes, and the solution becomes weaker. When a Winchester of ammonia is received from the wholesale chemist the stopper of the bottle is generally luted with almond, oil, linseed, paste to prevent the escape of the ammonia. The bottle be thin, and of glass, and it is stored in a warm room, it may burst from the internal pressure. The safest and best way of dealing with ammonia when required for photographic uses is to at once dilute it with an equal bulk of water as soon as received from the dealer or chemist. It is then comparatively harmless, and double the quantity can be used in making up the formulæ. There is another advantage in doing this. Each time a bottle of .880 ammonia is opened some of the gas is liberated and escapes, consequently it gets weaker every time; but when it is diluted with an equal bulk of water, its strength is practically constant, and can be relied upon, supposing the bottle is always kept properly stoppered.

**Sight testing opticians.** Some three or four years ago the Spectacle Makers' Company, following the example of some of the old City Companies, who have taken steps with a view to improving the crafts they are supposed to represent, decided to grant certificates of proficiency in sight testing to opticians who were successful in passing their examination by a committee of experts. A Bill has now been introduced in the House of Lords, by Lord Addington, entitled "An Act to regulate the practice of opticians as regards the testing of sight." The Bill, as now printed and issued, is evidently the outcome of the action of the Spectacle Makers' Company, for if it should become law it will enact that "any person who after the passing of this Act shall pass the examination in sight testing required by the Company, or such other examination as may from

time to time be approved by the Central Board, shall be entitled to be registered under this Act," etc. In the interpretation of the Act, "the Company means the Master, Wardens, and Fellowship of the Spectacle Makers of London." The Act, if it passes, makes it illegal for anyone to style himself a sight testing optician unless he has been duly registered as such, and the penalty for so doing is one not exceeding £20. Some of the clauses in the Bill are very stringent. For example, any person who procures, or attempts to procure, registration on a fraudulent declaration, certificate, or representation, will be guilty of a misdemeanour, and on conviction will be liable to imprisonment, with or without hard labour, for any term not exceeding twelve months. There is little question that the Spectacle Makers' Company have done, and are doing, good work in examining and granting certificates to those competent to test persons' sight in a proper manner, and their action will apply a check to the harm which is frequently done to persons purchasing spectacles unsuitable for them.

\* \* \*

**Warrington Exhibition.** On May 17 to 25 the exhibition of the Warrington Photographic Society will be held in the Municipal Art Gallery, a venue which should be noted by exhibitors, inasmuch as its selection precludes the Society from charging for admission, and therefore a good attendance may be expected. A further incentive to exhibit is provided by the offer of the Society to collect frames from the Northern Exhibition at Manchester. There is thus every prospect that the Warrington people will bring together a very good collection. The class for those who have not previously taken an award should encourage a large number of beginners, and scientific workers may note that lantern slides illustrative of one subject will be received for one fee in the scientific class without regard to number. The entry forms and all other particulars may be had from the secretary, Mr. B. C. Smithson, 13, Chester Road, Warrington.

### THE INVENTION OF SELF-TONING PAPER.

THE letter from Mr. H. Bachrach, of Baltimore, in our last issue touches a point which, so far as our knowledge and reading go, has not been noticed in works or papers dealing with the development of photography from the historical standpoint. The principle of a self-toning paper, one would have supposed, would have been enunciated in the fifties or sixties of the last century, inasmuch as during the early part of the period covered by these two decades the practice of toning and fixing very closely resembled the operations now customary in treating papers of the popular self-toning class. Following closely on the processes of Fox Talbot, it was found that a fixing solution of hyposulphite of soda which had been in use for some time, and had thereby accumulated a certain proportion of silver salts from the prints, together with some free acid, was able to impart a cold tone to prints, whilst at the same time fixing them. Some years elapsed before it was recognised that this toning was due to decomposition of the hyposulphite, was brought about by the formation of silver sulphide, and was almost invariably fugitive in its results. Prior to the introduction of alkaline toning baths the tone-

fixing bath of hyposulphite of soda and gold chloride was largely employed, and proved capable of producing lasting results. It would have been a natural and easy step from this procedure to the use of a plain hyposulphite bath and the incorporation of the gold in the sensitive material. Yet we must confirm Mr. Bachrach in his claim to have been the first to have worked and published such a process. Such was our first impression on perusing his letter, which appeared in our last issue; nor are we able to discover any publication of a similar nature which ante-dates his paper in "Wilson's Mosaics" for 1888. The only item in earlier photographic literature which may be taken as suggesting a self-toning paper is contained in a work on "The Dry Collodion Process," by Mr. Robert Freeman Barnes, published by R. F. Barnes and Co., New Bond Street, W. In a second edition of this manual, which appeared in 1857, are some supplementary notes on printing processes and other matters, in the course of which the author comments on mercury bichloride (corrosive sublimate) as "calculated to rank high as a fixing and sensitising agent." He impregnated salted paper with the mercuric chloride by floating on a solution of the sublimate, and he subsequently sensitised with ammonio-nitrate of silver. The passage which follows might almost be read as instructions for the use of self-toning paper in the present day:—"The picture must be printed exactly to the depth required, as it is not reduced afterwards in the hyposulphite. The prints when taken out of the frame are reddish in colour: on immersion in the fixing solution they rapidly change to a beautiful blue-black." The fixing bath here directed, however, is a strong solution of hyposulphite containing three or four grains of gold chloride in each pint. Except that the mercury appears to have accelerated the toning process, there does not seem to be anything in Barnes's method worth describing as formulating a "self-toning" principle. It is quite possible, however, that it is the process of which the late Traill Taylor had some recollection on the question of self-toning being broached to him by our correspondent of Baltimore.

In 1864 there appeared in "Photographisches Archiv" (p. 288) a process which is very similar to Mr. Bachrach's. It is described as "Hennah's," but although gold is included in the salting solution no mention is made of its self-toning properties, nor any reason given for the inclusion of the gold in the salting solution. The article reads as though the process were well known at the time. The paper was salted on:—Gold chloride, 1 gm.; ammonium chloride, 2 gm.; water, 160 c.c.s.; and whilst still somewhat damp floated on ammoniacal silver bath containing 18 gm. of silver nitrate in 150 c.c.s. of water. After printing it was laid in water, 500 c.c.s.; hypo, 125 gm.; silver nitrate, 1 gm., to which was added also 25 gm. of the sensitising bath. The prints were immersed in it without washing, removed after one hour, and washed in boiling water. When dry they were flattened out and pressed with a hot iron, though as to whether this part of the process was necessary for the toning nothing is said. In fact, as not a word is said from first to last it is not easy to understand why Dr. Eder in his "Handbuch," Part IV., page 105, should discuss the claims of Hennah to the enumeration of the self-toning principle.

As "Photographic Mosaics" is but little circulated in this country, although at one time a popular annual in America, it may be worth while to quote the portion of Mr. Bachrach's paper relating to the self-toning process. He writes:—"About twenty years ago I conducted a long and exhaustive series of experiments to com-

bine the gold with the sensitising solutions on the paper, and thus tone automatically: the operation being completed in the fixing bath, the tone to be determined by the amount of gold used. In this operation, of course, the entire body of reduced silver in the picture was thoroughly converted, not merely on the surface as in the toning methods now used. Without going into the chemical theories and reactions on which I based my ideas, I will confine myself to the results obtained so far as I went: for I was compelled to drop these experiments in the active duties of business which followed. . . . On plain paper I succeeded perfectly, but on albumenised paper, though some fair results were obtained, I could not work out a practical method. By adding two grains of pure chloride of gold (previously neutralised with chalk) to every ounce of the salting solution, and silvering with ammonia-nitrate of silver as usual, the print came out of the frame ready-toned, needing only the washing to rid it of free nitrate and fixing in the hypo solution, *no toning being needed*. The tone with this quantity of gold is a perfect black with warmer half-tone. A less quantity will give a warmer tone. Every print is, of course, toned alike by this process. I must add that I found it necessary, in order to avoid bad results, caused by the amount of chlorine set free by the combination of silver and gold, to add one grain of bromide of potassium to each ounce of the salting solution, which gave prints retaining every detail in the negative. But with albumenised paper I found almost insurmountable difficulties. No combinations that were tried could make gold chloride combine with albumen properly. After numbers of fruitless experiments I used an alcoholic solution of neutralised gold on the commercial albumenised papers, and the results obtained proved that success was possible, and, in fact, certain, if a different salt of gold, one containing no chlorine, could be made for the purpose."

The patent referred to by Mr. Bachrach is no doubt that of Louis F. Marten, St. Charles, Missouri, applied for on October 22, 1899, and granted October 21, 1890 (No. 439,021). The distinctive features of the process are stated by the inventor to be the toning of the prints without the usual gold bath, uniformity of tone, and saving of time and labour. The preparation of the paper is to be carried out on the following lines:—15 grains of ammonium bromide are dissolved in three ounces of water, 180 grains of gelatine added, and the latter allowed to soak for fifteen minutes, after which it is dissolved on a water bath kept just below boiling. One grain of gold chloride dissolved in three drams of nearly boiling water is then added, and then 75 grains of silver nitrate dissolved in one ounce of water, also nearly boiling. Nitrate of ammonium, 95 grains in three-quarters of an ounce of water are mixed with two grains of gold chloride in two drams of water, the mixture heated to nearly boiling and added to the first solution. Citric acid (75 grains) is next dissolved in half an ounce of hot water, heated and added, and then, finally, 150 grains of gelatine are placed in a vessel, the above mixture poured over it and kept warm until the gelatine dissolves, when the emulsion is ready for use, and is employed in its warm state to coat the paper.

It was held essential by the inventor that nitrate of silver, chloride of gold, and a bromide salt should be used in connection with other salts in conjunction with a colloidal vehicle, to form a good printing surface.

The coated paper was ready for use when dry. It was printed deeply, rinsed in one or two changes of water, and placed in a bath containing one grain of ammonium sulphocyanide in each four ounces of water in which the toning took place. The prints were then fixed in 1:6 hyposulphite of soda and washed as usual.

## PHOTOGRAPHIC PORTRAITURE BY R. DÜHRKOOP.

An exhibition of the examples of Herr R. Dührkoop's work which opened at the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY last week has already been visited by a number of professional and amateur photographers, to whom, we

understand, the photographs have appealed in a manner which has convinced our own judgment of the photographs as an object of study for English workers. The technique by Mr. Tilney which is printed below may be profitably read before paying a visit, as it represents the view of an artist and critic approaching the collection free from bias one way or the other, and anxious only to discover from what causes the pictures on the walls derive their effect. Herr Dührkoop, it may be interesting to mention, is no newcomer in the ranks of professional photographers in Germany. For almost the whole of his life he has been in business in Hamburg, and until some ten or eight years ago was content to produce a kind of photography which may be seen in the windows of good photographers in that country in Great Britain. His present position of a leader in his profession arises from his discernment of the fact that there is a public which would

respond to his offer of a different kind of photography, of a class which aimed at individual portrayal of his sitters and involved the banishment from the studio of the whole stock of the usual accessories or furniture, and a complete revision of the style in which each photograph is presented to the customer. Some five years ago Herr Ernst Juhl, a critic of German photography and photographers, wrote in "Photograms of the Year" an article in which he took a pessimistic view of the progress towards a recognition of art principles among the professional photographers of his country. Dührkoop he singled out as one of only three or four photographers in all Germany who rose above the dead level of their contemporaries. Since that time Herr Dührkoop has shown himself capable of a variety and originality which, perhaps, his preciator did not completely realise. And the fact must be stated in connection with this development that it has been limited to a large business. Herr Dührkoop has his studios and establishment in the Hamburger-Hof, the handsomest block in the city, and he is opening, about the time these lines appear, a house in Unter den Linden, Berlin. He issues no price list, though he has a fixed scale of charges. If the price

is too high for a customer, he or she is politely told that he is compelled to decline the commission, a course which, in his experience, has the desired result of leading the would-be sitter to return sooner or later. On the other hand, if the

result of a sitting is not to a client's liking, he is liberal with the sittings, and agreeable to leave it to the sitter whether an order for copies follows from the negatives which have been taken.

The individuality which is aimed at in all the portraiture done in the studio or at his sitters' houses—a great deal is done in the latter—is continued in the final mounting of the prints. Herr Dührkoop uses not a single commercial ready-made mount in his business. Each photograph, or set of photographs, is supplied, mounted on a stiff paper and contained in a folder which is lettered by hand with the initials of the sitter, surrounded by a simple decorative design, and if a dozen folders are issued to a customer the design on each will be different, and the mounting of the prints likewise varied by ringing the changes on the mounting papers, which Herr Dührkoop purchases to his special order from America. The whole aim of the business is to do the thing as well

R. DÜHRKOOP. Portrait by J. C. Strauss, St. Louis, U.S.A.

as it can be done, and to show the customer that he is getting a photograph which has a character of its own not only in its treatment of his features, but in the details of printing and mounting. The only forms of enlarged portrait which we saw displayed in Herr Dührkoop's studio were in carbon and gum. The latter process is used by him to very good effect for portraits of sitters of striking appearance.

Possibly one secret of Herr Dührkoop's success has been, and is, his open mind. He takes the broad view of a cosmopolitan, and that he is to a greater degree than many of his contemporaries. He spent a year in France when in middle life, has travelled in England, and visited the St. Louis Exhibition last year, when the photograph we reproduce was taken by Mr. Julius Strauss.

Reproduction of Herr Dührkoop's photographs is not at all an easy matter, for the majority embrace a very long range of tones, the gradations of which in the shadows defy satisfactory rendering by the half-tone block. Therefore, we hope that the supplement which we present with this issue will not lead our readers to under-estimate the original, which is a remarkably fine piece of photography. It represents an uncon-

ventional form of indoor portraiture of which there are several examples in the present exhibition. Of Dührkoop in lighter vein we should have liked to have laid some specimens before the reader, but the originals themselves are the best means of making the acquaintance of these spontaneous achievements

with the camera. As we have before announced, the exhibition is open from 10.30 to 4.30; on Saturdays, from 10.30 to 12.30. For the convenience of those who cannot visit it during the day time, it will be open every Wednesday evening from 6 to 8.

### AN APPRECIATION OF DÜHRKOPF'S PORTRAITURE.

HE who would succeed in these grievously competitive days must do something new. This simple fact is so well understood upon all hands that the application of the principle it imposes has given rise to an ever-widening stream of surprises. Especially has the amateur photographer sought to leap into popularity by the production of works calculated to arrest at all hazards. In a general way, it is not given to the professional photographer to play those pranks with the portraits of his sitters that the amateur may play with his landscape subjects, where a likeness to the original is of the very least and last importance. He could not, even if he would, adopt those oddities of treatment by which the unprofessional man stops the wandering gaze of an onlooker. And it is a very good thing for him that he cannot.

After all, there is small merit in eliciting such a remark as "What a queer thing!" Queer things are for collectors; customers want fine things. But so great is commercial pressure, so great the danger of being passed over, and, again, so great the desire on the part of the jaded public for new sensations—a quite natural vitiation of appetite caused by a diet too varied and highly spiced—that the queer has latterly been found a very successful substitute for the fine. The truth of this must be admitted whilst it is deplored.

#### Newness Without Queerness.

But—just as if photographic art had suddenly grown sick of masquerading in motley, and had flung off the absurdities with which her sham votaries had loaded her—we are made aware of the work of one who for years past has been producing portraits the sane and simple beauties of which take us by storm far more completely than do the bizarreries of some amongst us whom we have been expected to honour.

The work of Rudolph Dührkoop is as new as that of the most modern; but its newness is all of charm. It is fresh in its outlook upon life and its appreciation of character; but it violates no probabilities. What it lacks absolutely is a striving after the unusual.

In support of our words we may refer to the study entitled "An Interesting Book." In this a young girl lies along a couch, having dropped from a sitting posture to within eye-range of a book which lies open upon the seat. The pose is certainly not one that would be chosen for the purpose of reading, and therein is its unconventionality. Nevertheless, the pose is at once graceful, taking, and, above all, natural. Youth finds ease and comfort in postures that to the mature would be as apoplectic gymnastics. Hence the perfect truth of this picture pleases as much as does the "out-of-the-wayness" of the idea. These remarks apply with equal force to No. 65, "Waking up."

#### The Freshness of Commonplace.

Perhaps it is not too much to hazard that the worldly and artistic success of Herr Dührkoop is attributable to the very ordinary nature of his themes, which appear to be just exactly those of an ideal portraiture in this workaday world. For his sitters are seen as they are in their homes; not glorified by a special "get-up" for the occasion, or transfigured by freaks of light and shade called up by the photographer. They have mostly all the anatomy they were born with, suffering no amputation of ears or hair, limbs or flanks. Their heads are as much "in the right place" on the prints as was the photographer's on his shoulders when he took them.

In the frank and unsophisticated group showing "Herr Georg

Reicke and his Family" at their meal-table; in the two or three mothers with their sucklings; in the children breakfasting, playing, laughing, yawning, or performing other physical functions that little ones do with such charm or comicality; in all of these, and there are many, we see the apotheosis of domesticity.

#### Posing Without Poseyness.

Equally noticeable is the absence of posey self-consciousness that Herr Dührkoop manages, by some miraculous means, to achieve in such hopelessly difficult subjects as a pair of lovers reading, or holding hands seated upon a sofa, or kissing. In these, as well as in the studies of advanced age, such as "The Old Bible," in which the slow-spelling out of comforting texts is admirably shown by the puckered brows; a healthy interest is displayed in the phases of humble or middle-class life. Such an interest is a true echo of the spirit which prompted the early Flemish painters. It is no new thing, perhaps, to imitate an old Flemish painting by photography; but it is certainly a new thing for the camera to approach the humdrum of courting couples without giving way to either facetiousness on the one hand, or to sentimental romancing on the other. It is this contentedness with everyday things as they are, this serious view of the matter around him, contemptible by familiarity to the ordinary mind, that places the works of this photographer in the same category with the painted works of Jan Steen, Terborch, and the elder Mieris; and the attitude of mind that makes this possible is new in photography.

#### The Value of Tradition.

Another secret of Herr Dührkoop's excellence lies, we think, in his firm stand for what the world, during the last three hundred years, has accepted, and still continues to accept, as good in principle. Apparently he sees no advantage to be gained in letting the traditions of art go by the board. Accordingly, his portraits have that dignity of style and beauty of arrangement characteristic of the best examples of painted portraits in all periods. He is evidently not one to "snort defiance" at painters, and as a consequence many of his works remind us of portraits reproduced from Rembrandt and Vandyke, especially those that depict the civic functionaries in ruffs—counterparts of the seventeenth century article—and robes. We strongly recommend a lingering examination of the photogravure prints in the large volume published under the title of "Men and Women of Hamburg at the Commencement of the Twentieth Century." The heads in these portraits seem exactly to be just such as we have seen again and again over such ruffs in the works of antiquity to which we have referred.

#### Character in Likeness.

We should very much doubt if Herr Dührkoop has put himself out in the slightest degree so to manoeuvre things that his sitters in official costume shall look like the men of three hundred years ago; but this we are certain he has done: he has striven first of all to get a literal likeness rather than a shadowy sketch of his sitter. He has endeavoured to pack all the character that the subject possesses and is known for into the record that the camera gives. In this seeking after the inner man as well as taking the outer, the photographer is exactly on the footing of Rembrandt and Van der Helst, and as a natural consequence we are reminded of the works of those masters. Now, whilst the modern professional relies so much upon the beautification of his sitter, and that largely

the pernicious practice of retouching, it must follow that nothing like the real character of the subject is placed beyond range of possibility.

### Professional Prettiness and Amateur "Art"-iness.

The inanities that must result from all methods that give character the go-by are as deplorable amongst professionals as the impertinences put forward as art are reprehensible amongst amateurs. Both are equally unworthy, but perhaps the latter are the more blameworthy because of the lofty claims in which they are flaunted.

The works of Dührkoop even are not absolutely immaculate in this respect; for we remember to have seen the portrait of a famous author writing in a scheme of illumination that sane *littérateur* would adopt; but this no doubt was only to beat the modern amateur on his own ground. At any rate, it does not give us those great coarse faces, larger than life, and all but impinging upon the mount, nor those shadowy faces that stare vacuously, like creatures of a bad dream. It is always a human that he gives us. Abjuring adventitiousness to popularity, he has no need to strain after effect, albeit the effect is never absent.

### Sun Spots.

We have taken exception to one work, and we might as well sweep what other objections we have into the same paraphrase, lest the captious say that we see no spots on this sun, from before which we are proud to have the privilege of withdrawing the cloud of obscurity hanging between him and Londoners.

Our most serious complaint is that in the picture numbered 57, and entitled "Remembrance" in this exhibition, there exists one of those pictorial solecisms that photography and ancient Chinese art have hitherto shared between them, but which is fair to encroach upon the thoroughbred Western stock also. We refer to the violent perspective of the floor. This is the effect of jutting the corner of a carpet right up gable-end into the field of the picture. Why? What is gained? We have a light foreground devoted to the large-scale, well-defined presentment of what is perhaps the least important element of the whole pictorial material. On the other hand, what is lost? The real object of interest, next to that afforded by the figure of the woman who stoops over an open drawer, is a piece of interesting furniture of which the drawer forms part. This, however, is ruthlessly cut off by the top margin of the print.

Unfortunately this practice, originating in a blunder, has now become so common that our minds often accept it without protest, and so the thing is allowed to go on. Its reduction to absurdum is seen often enough: a tiny distant spot of interest placed along the top edge of a picture, and all before it literally a waste of foreground.

### Figures Without Faces.

Another principle is called into question by the picture of a mother and child called "Sunshine," No. 58. It may well be asked whether people are really more glad to see the backs of heads than faces, assuming, of course, that the faces are of average human interest. When back views have been painted it has usually been for some especial study of the nude in this aspect. We never remember to have seen a Madonna and Child with the faces turned away; nor, indeed, any subject relying for its interest upon such human and natural charm as a mother fondling her child. Of all such interest No. 58 is empty. The heads appear to be blanks,

### The World's Debt to Photography.

When compared with the other subjects in the same series the loss of this human interest is more keenly felt than ever.

Nothing could be more moving than the sweet and solemn solicitude of the mother who kisses "Her Child" in No. 57, that hangs next. It is for such happy things, so elusive before, but so easily caught fast now, that the world will ever owe an increasing debt to photography. Study the contrast of emotion in the youngster's expression. He, or she, waits with the elevated eyebrows of calm resignation, whilst the mother makes those demonstrations of adulation which maternity never can suppress. Similar in motive is No. 70, which bears the name of "Maternity." The contrast of expression between the woman and the babe at her breast is remarkable. The little feeder looks up, conscious of something unusual going on during the function, and not a little apprehensive of the camera perhaps. In this, again, the lighting is well thought out. It falls in its fullest strength upon the mother's bosom.

### Straightforward Photography.

But particular instances only beg the question of general merit. Where Herr Dührkoop excels farthest, in our minds, is in the surprisingly artistic results of his works considered pictorially. This is due, we believe, to the straightforward use of well-established photographic methods. He would seem to have decided that the regular ways of photographic procedure are inexhaustible; that new plans and processes offer no extra advantages to a man of resource and artistic appreciation. Accordingly he is not found travestying nature. It is in his approach to the subject that he is new and great. His studies of child life open a new door. We have had pretty children often enough; children reading, playing, or eating; but we have never had them caught red-handed, so to speak, like this before. It is evident that here they have not been told to look nice, to turn their toes out, shut their mouths, or otherwise to behave themselves like good children. No one would ever confess to feeling the slightest evidence of the camera in the older children; and in the babes, where it may occur once or twice, it is of course half the charm, and has not been avoided.

### Virility and Spontaneity.

Spontaneity is similarly welcome in the character studies of old peasant women, knitting, gossiping, or comporting themselves with a natural ease that is delightful. In the portraits it is as much in evidence. We cannot point to one that shows self-consciousness to any damaging extent. Most of them are virility itself, and, moreover, given with that old-masterlike attention to a fitting environment and occupation which makes a portrait so much more interesting a document to those for whom it is to become a treasured possession.

Herr Dührkoop likewise fills up his prints with matter, and that of a sort that is valuable to the pictorial whole. He understands what so few to-day trouble themselves to understand: the precise meaning of the term breadth.

### What is Breadth?

Broader effects of light and shade we have never seen! Such absence of tonal vacuity and "space to let" we have never seen either! Moreover, we may as truthfully add that such wealth of detail we have never seen! Detail in its right place and in its right tone is a glory; it is nature! Do we grumble at the forms of mosses on a tree trunk? There is no reason why, in photography, detail should ever be in the way. It is never in Herr Dührkoop's way, and he revels in it at times. With the painter it may be different. His work does not gain by laboriousness, which is the only way in which he could emulate the camera if he wished to. To get breadth he is compelled to suppress detail, for physical reasons, not necessarily for artistic ones. The camera man shows his weakness, not his strength, when he goes and does likewise.

### The "Grand Style."

In the matter of composition and arrangement, also, these photographs show a fine style. They have always the "large line." Being for the most part full-lengths, or three-quarter lengths, they possess opportunities for the disposal of a sitter's limbs and garments which are denied to the decollated head or the butcher-like divisions of humanity that have become the vogue latterly.

The placing of a figure upon the canvas is always a matter of great importance to a painter; but photographers give the matter no thought, as a rule; at least, it is hard to discover

in their results. Herr Dührkoop is a brilliant exception. The portraits in the book, particularly, show a keen appreciation of this important matter.

A similar respect for the traditions of the art is shown by the well-designed lighting upon the figures. No. 48, a portrait of Bracony, the sculptor, is a good example. The strength and subtlety of this piece would, we are convinced, have given Rembrandt a thrill of joy.

It is to be hoped that Herr Dührkoop will be considered a model for all aspirants.

F. C. TILNEY.

### THE PRESS ON THE DÜHRKOOP EXHIBITION.

"The characteristics of these photographs are directness and simplicity, combined with superb technique. The pictures are subjects well within the range of every amateur photographer, and we wonder with what success would the average English professional tackle similar pictures to those included in the show. We have, of course, professionals of the calibre of Furley Lewis and T. Lee Syms, who would treat these subjects in their own characteristic manner, but it is in the ranks of our leading amateurs that we are most likely to meet with exponents of the style indicated by the German professional."—"The Photographic News."

The artist, we consider, is at his best when dealing with portraits "at home," some very remarkable and effective examples of lighting and posing being shown. Seventy-seven prints, all beautifully mounted and framed in the passe-partout style, are hung on the walls, and about 200 are contained in a portfolio.—"Focus."

"A very fascinating exhibition of the distinguished work with the camera of the Hamburg artist, R. Dührkoop—the name appears to be Dutch—is now being shown at the office of the BRITISH JOURNAL OF PHOTOGRAPHY, in Wellington Street. His work will be familiar to those who visit the Photographic 'Salon.' He excels in the pure art of portraiture, and his skill in invariably getting a real pictorial effect is very marked. There is a splendid portrait of Joachim, and

a group of the two brothers, O. and J. A. Repsold, which is at once natural and vividly striking. Several most lifelike studies of children make a highly distinguished and most characteristic show of genuinely artistic photography."—"Evening Standard and St. James's Gazette."

"To me the pictures appear to be sound rather than inspired. The photographer is one who has with sure hand steered a safe middle course. Take, for example, his home portraiture series; they form a kind of compromise between Ralph Robinson and Alvin Coburn. They are neither sugar nor salt, but just pictorial sherbet, which no doubt many people will find most refreshing."—Hector Maclean, in the "Morning Post."

"Some of the genre pictures are wonderfully lifelike, and free from constraint or conscious pose. The portraits also betray no evidence of the photographer's unnerving presence. The sitters are perfectly at ease, putting on no "side," and having apparently no dread of that trying moment when the demon of the atelier cautions them not to move by shouting the monosyllabic "Now." This is one secret of the success of the portraits on view, the originals being caught at their happiest moments before they have time to distort their features and become as stiff and as lifeless as waxworks."—"Morning Advertiser."

## AMERICAN PHOTOGRAPHERS IN CONFERENCE.

### THE CONVENTION OF THE PROFESSIONAL PHOTOGRAPHERS' SOCIETY OF NEW YORK.

A two days' Convention was held in New York on April 5 and 6 of the Professional Photographers' Society of New York, under the presidency of Mr. Dudley Hoyt. We gather from the reports of the proceedings in our New York contemporary, "The Photographer," now the official organ of the P.P.S. of N.Y., that the Convention appears in every way to have been a marked success. The formal business was transacted at the Hotel Astor, and the list of conventioners includes nearly all the best-known men in the States. The general feeling appears to be that the Society has responded to the needs of the time in frankly ignoring topics of art and technique, and applying itself to the business problems which confront the photographer. Such a special programme is a new feature in American conventions where, however, the business aspect of photography has not been altogether ignored; but the direct aims and objects of the Convention have been business.

For the first time, we learn, the subject of prices was discussed.

For the first time subjects of every-day business interest in the photographic studio held the attention of a photographic body for hours.

For the first time in many years no paid orator swung his arms and displayed his ignorance of photographic topics. There were no set speeches, the word art was not mentioned; all precedent was ignored and the subjects for discussion were selected and debated upon by the members themselves.

The Presidential address which we reprint below outlines a plan of unit organization, perfectly conceived and admirably explained, which may be studied in this country just as diligently as in America.

The "single-picture" exhibition, on which we have already com-

mented, was a great feature of the Convention. One leading photographer described it as "the most magnificent success and the grandest failure I ever saw," commenting on which the "Photographer" says: "It was both. The idea as conceived was unquestionably right. One hundred and sixty-five members of the Society thought so and sent pictures; thirty-four thought otherwise and did not. The thirty-four comprised the prominent New Yorkers whose pictures would have added greatly to the interest of the exhibition. As a result the Society abandoned the price feature for the next exhibition.

But the single picture exhibition, price included, has appeared. It was radical, new, revolutionary, and above all else, practical. If the exhibitions of the future keep pace with the new convention movement, a movement that spells an honest interest in the welfare of the mass, the matter of price must be included in the plan. Scores of men spent hours in front of the incomplete show in the Astor, note book and pencil in hand. These men represented the mass of photographers, and they took home with them far more than appears upon the surface. The pictures shown were extremely interesting; some of them were extraordinarily good, and the valuable feature, the most valuable feature, was the style letter that indicated the price at which the pictures were to be sold.

The exhibition next year will be a single picture exhibition without limitations. Each member will be asked to send one picture, and that picture will be hung. The same men who supported the exhibition this year will support the one next year. It will be a splendid show, and from the standpoint of pictorial and technical interest will surpass anything of the kind ever held in this country. From the standpoint of practical business interest it will be of little value.

Differences between the two parties upon the question will do  
t will put both parties on their metal, and every man is going  
an exhibition next year for blood.  
rint below the address of Mr. Dudley Hoyt, who is succeeded

in the presidential chair by Mr. Pirie MacDonald, who was one of the  
founders of the Society, and who has himself worked with all his  
power for the furtherance of his objects. The Secretary of the  
Society is Mr. Curtis Bell.

## ORGANISATION FOR PHOTOGRAPHERS.

[The Presidential address of Dudley Hoyt, before the Convention of the Professional Photographers' Society of New York.]

**MEMBERS:**—The year which has elapsed since last we met  
en filled with happenings of importance to you and the photo-  
ers of the country. The nation has been blessed with pros-  
and the photographers have had their share of the good  
We are in a better condition as a Society and as members  
profession that grows in standing and importance in the com-  
with each succeeding year. Individually our members have  
ed with the times. Better pictures are being made to-day than  
fore in the history of photography, and in both the technical  
istic channels of effort we are ahead of the world. But, in the  
ment of this position we have, to a certain extent, lost sight of  
ic conditions. In bettering our product along modern lines,  
ring better pictures, we have increased the cost of production;  
sented to the public a studio in keeping with the work turned  
e have been compelled to increase our expenses. Competition  
profession is as keen as in other lines of business, and there-  
e man who lags behind, the man who does not put up a front,  
ut of line and is heard of no more.

pite of these added drains upon the photographer's income there  
en no material change in the size of that income. In 75 per  
of the studios in this state investigation will show that while  
oss income over a term of years has remained practically the  
the expense column has been steadily mounting. It costs the  
graphers of this state more to do business to-day than it ever  
the past. As a result, we hear all over the land the cry that  
photographer is the poorest paid professional man in the com-  
y. To some extent the statement is true. What is the reason?

### On the Work of the Society.

the solution of this question the work of the Society for the  
several years must lie. Herein is our work.  
the State of New York there are about seven hundred profes-  
sion photographers, of whom practically 50 per cent. owe allegiance  
r organization. This, for an institution of barely two years'  
h, is a remarkable showing, and one that indicates to me the  
that the photographers of the state are ready for the tasks which  
ont them. The progress of an organization such as ours must  
sarily be slow. Strength and stability are not born in a night,  
he steady, well defined growth of our society speaks well for its  
e. In two years we cannot expect to enrol more than a major  
of the professional workers of the state, for there will always  
ertain element who cannot and will not see the advantages of  
eration. But there is still a great deal of hard work before  
members. Gradually every man in the state susceptible of im-  
ement must be gathered into membership. Prejudices must be  
ome, the members of the profession at large, not now with us,  
ince that this organization is capable of helping him, and the  
-worn feeling which has so far prevented progress must be  
ved.

### Personnel of the Membership.

in this connection we are confronted with a condition found no-  
re else in the Union. In New York City there are more profes-  
sional photographers than there are in many of the states. Their  
ests must of necessity be somewhat different from those of the  
state members, who in nowise differ from the great army through-  
out the country. It therefore becomes necessary for us to so conduct  
affairs as to harmonise these seemingly conflicting elements, and  
so to the men of the Metropolis and the men from up-country must  
make concessions. We are trying to help the whole body—to  
e it possible for all members of the profession to enjoy a share  
prosperity, and I feel that our members are big and broad enough  
arry out the task without further friction than is necessary to keep  
the feeling of independence and of loyalty to sectional interest.

### Unit of Organization.

its youngest days the Society realised that it could not accom-  
much in the way of helping the photographic profession if its  
k was carried out along accepted lines. Most photographic  
nizations meet once a year. As a result these meetings partake  
e of the nature of a reunion of old friends than of a session of

men, meeting for business purposes only. Hence it was decided to  
incorporate a wheel within a wheel, or rather wheels within a wheel,  
and to this end the state was divided into three sections—the Metro-  
politan, the Central, and the Western. In each of these sections a  
local organisation was perfected, with meetings once a month.

Because it is relevant here, and for the further purpose of acquaint-  
ing those unfamiliar with the work of the Sections with what has  
been done, I shall give a brief resume of the transactions of the  
Rochester Section, with which I am, of course, most familiar.

This Section, over which your President has presided during the  
past year, has held regular monthly meetings since May, 1905. The  
meetings have been liberally attended and little difficulty was ex-  
perienced in interesting the members of the profession residing within  
the circle covered by the Section in the work of the body. During  
last summer the Section reached an agreement as to Sunday closing,  
and during the whole of the season the proprietors and their em-  
ployees had one day which they could call their own.

### Agreement on School Work.

An agreement has also been reached with reference to school work,  
a class of trade which had in former years effectually demoralised  
prices in the city. To-day there is a definite agreement as to prices  
and a uniform discount arranged, graded upon the number of persons  
contracted for, and harmony exists where before there was chaos. A  
number of evenings devoted to practical experiments were greatly  
enjoyed by the members, notably those in which domestic lenses  
and the value of artificial light were discussed. At one meeting a  
collection of ready-to-deliver pictures from a score or more of the  
foremost photographers of the country outside of the State were  
exhibited. Particular attention was given at this meeting to the  
mailing devices, pasters, string, protective board used in mailing the  
packages, as well as the pictures themselves, and considerable informa-  
tion of practical value was gained.

### Good Fellowship Between Members

The one thing that has impressed me at these monthly meetings  
has been the good fellowship engendered from the association one  
with the other. Absolute proof has been furnished that the photo-  
graphers of this state are beginning to recognise their competitors,  
are making it a business to know each other, and to know each other  
as friends. In these three sections I wish to point out to you the  
extraordinary fact that photographers have been meeting socially  
once a month, talking about the most intimate business conditions,  
prices, studio rules, business relations with the public, the suppression  
of objectionable features, and above all else maintained a cordial  
relationship which has, in my experience, never before been ex-  
perienced in the photographic business.

### Extension of the Unit Plan.

In an open letter addressed to the members of the Society last  
November, I called your attention to the advisability of extending  
the unit plan of organisation, so that the same valuable features of  
the local section will apply to a wider territory and reach more of  
our members. Necessarily the present local sections reach but a  
limited amount of territory. It cannot be expected that members  
living remote from the meeting places of these sections can attend the  
meetings regularly. I therefore suggest to you that sub-sections or  
divisions be organised in every locality where there are a sufficient  
number of photographers to warrant such action.

I am glad to say that encouraging communications have been  
received from several towns not in the immediate territory of the  
three present sections, and I am confident that the present year will  
see growth in this direction.

To cement the relationship of these sub-sections, one to the other,  
and at the same time to keep alive the interest in the parent organisa-  
tion, the State Society, I suggest that the present local sections be  
kept intact and that the sub-sections or divisions be made a part of  
them.

The following plan is suggested as a reasonable basis upon which  
to perfect the organisation:

Sub-sections, to be known as districts, to be organised in all towns and communities capable of supporting them. Meetings to be held once a month. The three present sections to meet once a month as usual, with the exception of every fourth month, which should be a general meeting of all of the districts in the section. In other words, there should be a meeting every four months of all members of the Society in each of the three sections, these meetings to be held preferably in the town or city of the parent section.

The dates of the General Section meetings should be so arranged as to bring the entire society together for the annual meeting in New York. Thus there would be a monthly meeting in each district, a meeting every four months in each section, and the annual meeting in New York. In this way I believe that the best interests of every member will be conserved and the Society made of real and permanent value to all.

A uniform constitution and set of by-laws should be formulated by a committee appointed for the purpose, and such other incidental details as will assist the formation and ready conduct of the local meetings.

#### Importance of Development Work.

I have no hesitancy in saying that I consider the development of the Society along these lines as the most important work to come before this meeting, and I wish to ask for the cordial co-operation of every member in formulating plans and devising means by which the whole State of New York will be dotted with sub-sections of the Society, each working for the benefit of its own members and for the good of the whole body.

For the purpose of making the meetings of the local sections and divisions more interesting, I suggest that means be taken to provide for an interchange of exhibitions between the different divisions. Committees should be appointed in each organisation to collect pictures and forward them to other sections. By proper arrangement of details it should be possible to have an exhibition of interest at nearly every meeting. The pictures collected in this way should be on artistic lines and should show progress in a definite direction. Viewed in this light the educational value of such an interchange would be of wonderful help.

#### The Labour Bureau.

During the past year the Labour Bureau, authorised by the last meeting, has been put into operation. Under the direction of the committee proper steps have been taken for the incorporation of the Society under the law of the state, and the final move will be made at the present meeting. Thus the conduct of a labour bureau will become a proper and legal adjunct of the Society. In the administration of its duties the committee having charge of the bureau has been hampered by the fact that some uncertainty existed as to its proper functions under the law of the state, and also by reason of the fact that the bureau and its work was new to both members and those seeking employment.

#### Reorganisation Suggested.

For the purpose of making this bureau of a more general and far-reaching interest to the members, I suggest that its organisation and conduct be extended to the local sections. To properly extend the work in this direction it will be necessary to employ a resident secretary, whose duty it will be to compile and collect the reports from the different sections. The secretary of each division should act as the representative of the bureau in his district and should be supplied with blanks in proper form. These blanks should be forwarded to the resident secretary once a week. This secretary in turn will compile the information received in this way and forward it to each of the local secretaries for reference. In this way it will be possible for the members to immediately consult the records of the bureau, without loss of time and with little trouble.

Every member of the Society should consider himself a working part of the bureau, and should furnish the local secretary of his district with all of the information with reference to men seeking employment at his disposal. All applicants for positions should be referred to the local secretary by the members.

As the bureau and its conduct will be of increasing importance its administration should rest with the executive committee. New rules governing the affairs of the bureau should be made, and I suggest the abandonment of the preliminary charge of one dollar made to each applicant for a position, and the substitution of a charge of

10 per cent. of the first month's salary earned by those who obtain positions through the Society's aid. One-half the sum thus obtained should be devoted to the compensation of the resident secretary, the remainder to the payment of such other expenses as are incurred by the bureau.

In addition to the concentration of interest on the part of members of the Society steps should be taken to acquaint photographers throughout the country with the work of the bureau and the photographic Press should be regularly informed of the progress made by the bureau. In addition to such matters as the bureau is enabled to have inserted in the Press, small cards, bearing advertisements of the bureau's objects, should be printed and distributed to the book houses throughout the state and country with an accompanying request that the card be displayed in a conspicuous place.

#### The Exhibition.

A valuable feature of our annual meetings is the exhibition of photographs. This year we have a "single picture" exhibition that should prove interesting to every member. The members were requested to send one print, which was to be hung, that print to be from a negative made in the regular course of business, and to be as typical of the "bread and butter" pictures produced in his studio as he could make it. By a careful survey of the exhibition you should be able to form a coherent idea as to the work of your fellows, and ample opportunity should be taken to analyse the pictures and discuss with your fellow-members such economic questions as may occur to you. I ask all of the members to contribute to the feeling that in these meetings the spirit of fellow-craftsmanship must rule, and that what one member can do to help another along will be done gracefully and gladly.

#### Studio Membership Cards.

Your Executive Board has had printed a membership card for display purposes in the studio. The committee asks every member to frame this card and exhibit it where the public can see it. It means an added peg in the game of professional prestige, and due attention should be paid to the committee's request.

The suggestion has been made that the Society issue a small metal plate bearing the same matter as the studio card, for display in the showcases. At the proper time this matter may be discussed, and if the Society so wills the plates will be issued.

#### The Question List.

Strong representations have been made to your President during the past year with reference to the consideration of a minimum price to be affixed to a dozen photographs. Necessarily in an organisation of this kind interest in this subject is divided, but from expressions I have had from an average number of all classes of photographers, I am convinced that debate upon the subject at this time is not only advisable but imperative. Your committee has therefore included in the list of published questions to be discussed at this meeting one covering the subject. The free discussion of prices is not according to precedent in photographic bodies, but precedent will be ignored in the conduct of these proceedings, and we shall attempt to get down to business without any more of the frills than is rendered necessary by the presence of our distinguished guests from other and older photographic bodies.

The list of questions which you have been asked to consider embraces many interesting factors in the every-day work of the photographer. At the proper time you will be asked to throw what light you can upon these matters, and I hope that every member will participate in the discussions. Please remember that these questions are suggested to you for the purpose of creating interest along definite lines. We must not hope to fire the Hudson or to correct matters and conditions which have been taking root for a half century. What we can do is to get the abuses into the limelight, where each and every one of us will have a chance to throw our respective bricks at them.

In the consideration of the questions which are to be considered I bespeak the careful consideration of the membership. The eyes of the photographic world are turned in our direction to-day. Let us try to accomplish something—a something that will live and expand for the good of the profession and of ourselves.

DUDLEY HOTT.

[Reports of the Society's conference will appear in our later issues.—EDS. B.J.P.]

PHYSICAL CHARACTERISTICS OF RELIEF ENGRAVINGS,  
ESPECIALLY RELATING TO HALF-TONES.

[A paper by N. S. Amstutz, in the "Inland Printer," to whose courtesy we are indebted for the engravings.—Eds., B.J.P.]

THE production and use of relief engravings have grown with tremendous strides in the last two decades. Especially is this true of half-tone engravings and line photo-engravings or zinc etchings. The term "relief engraving" applies to all engravings formed with raised printing surfaces. The existent half-tone is an outgrowth of a long series of efforts on the part of many investigators, who saw before them for many years what seemed an *ignus fatuus*—the translation of photographic tone values, consisting of variations in the density of chemical discolouration of a plane surface into a relief surface, with the aid of the camera, which should reproduce the seemingly evasive gradations of the photograph into raised printing points of variable size.

Of the principal qualities of half-tones that require the most careful attention, it seems important to put printing quality first, because if this is not up to standard, no matter how good the tonal values may be interpreted, the rendering goes for naught; secondly, should be placed tone values; thirdly, a full control of side etching, so as to preserve the tone values of the original, and also the mechanical strength of the dot; and lastly, an understanding of the broadening effect produced, even with the best printing.

Printing Quality.

This practically practical phase of the subject, obviously, depends on the depth of the etching, especially of the high lights. It may be defined empirically as being proportional to the reciprocal of the width of the widest groove, divided by the greatest depth of such groove.

A certain person connected in a business way with half-tone work when asked how deep the high-light depressions of a 120-line<sup>1</sup> engraving were etched, replied without hesitation and with much confidence: "At least one-thirty-second of an inch." Now, as a 120-line screen is only .00832 inch from centre to centre of line, and an allowance of .003 inch should be made for the width of printing face of a black dot, there remains but .0053 inch from the edge of one dot to that of the next, measured parallel to the screen lines; if measured diagonally, the distance is .0088 inch. Comparing the greater distance of .0088 inch to .03125 inch (being the decimal equivalent of one-thirty-second of an inch), the depth would be about four times greater, which is quite erroneous, especially when it is known, from measurements made, that the depth of etching in the high lights of a 120-line block is .0015 inch. This is approximately one-fifth of the diagonal distance between adjacent edges of the black dots. The off-hand estimate put it about twenty-one times greater than the actual depth.

The black dot at the end of a ten-minute flat etch of a 110-line screen with a given acid strength has a diameter of .0047 inch; after twenty minutes, or ten minutes additional, it has been reduced to .0037 inch, and after a total time in the acid of forty minutes the diameter is decreased to .002 inch.

The white dots in the deeper shadows of a 110-line screen have been enlarged in size during the time the black dots have been reduced, as follows: After ten minutes' etching they measure .004 inch across; after twenty minutes, .0047 inch, and after forty minutes, .0062 inch. The depth has increased at the rate of about .000035 inch per minute, making for a ten-minute etch a depth of .00035 inch, a twenty-minute etch .00070 inch and for a forty-minute etch .0014 inch.

The rate of etching, horizontal and vertical, is more rapid in the high lights than in the shadows, probably due to less isolation on account of gas bubbles. In the high lights at the end of ten minutes, for a 110-line screen, the rate of etching was .000065 inch per minute; after twenty minutes the rate dropped to .000057 inch per minute, and at the end of forty minutes it fell to .00005 inch per minute.

In the shadows the rate is practically uniform, but in the high lights it gradually lowers, though at its slowest remaining more rapid than in the shadows. It is probable that the increased number of metal particles released as the etching proceeds retard the free action of the acid toward the end of the etching. It is also probable that

acid vortices may be established around the black dots of the high lights, causing acid circulation and more rapid action than in the shadows. Irregularity in rocking and lack of attention to bubbles will very materially lower the rate of etching for a given time and seriously modify the uniformity of results, otherwise regularly attainable.

Associated with printing quality is brilliancy, a quality dependent on the relation of the area of the black dots to a unit area, enclosed by the sides of a square equal in dimension to the screen pitch, which with a 110-line screen is 1-110 inch, or .0091 on each side. Such a unit area comprises .0000828 square inch,<sup>3</sup> and if no dot occurred thereon would represent pure white.

Under the different times of etching, the black dots of a 110-line screen vary in area as follows: After ten minutes the area is .0000173 square inch, twenty minutes .0000135, and after forty minutes it is reduced to .0000032. The last, with a diameter of .002 inch, is used to illustrate how a "pure white" is modified by a black dot of such minute size. Remembering that a "unit area," mentioned in the previous paragraph, is equal to .0000828 square inch; omitting the ciphers, 828 represents a pure white, and when a dot of .0000032 square inch is formed therein, a part of the whole area is occupied by black; or, omitting the ciphers, thirty-two parts; then the black value is represented by 32-828 of the whole area, and white by 796-828.

Tonal Values.

Much has been done in Europe along the direction of determining the proper tone value of photographic reproductions. The matter can only be referred to in passing. These values concern the relation of the finished print to the subject of which it is a copy. The interpreting values are modified by screen and focal distance, diaphragm outline and side action during the period of etching. They require arbitrary treatment to compensate for the inevitable broadening of the dots in the process of printing. Proofs made from the specimens shown indicate an almost uniform spreading of .0005 inch away from the edge of any printing surface. It will be interesting to note how much this spreading action is modified in the high lights by overlays.

Side Etching.

After a "screen" negative is printed on to the sensitized surface of a metal plate, the unaffected portions washed away and those remaining burnt into an acid-resist enamel, the dot of remaining enamel in the high lights is of a definite diameter and area. It would retain these dimensions if there was no side action of the acid simultaneously to its etching into the plate. The rate of side action, and the consequent reduction in size of black and white dots, is given in Table A.

†At point 5, on Figs. 1, 2 and 3 (location shown on Fig. 4), at rates given in Table A.

The values in Table B apply more especially to the printing-quality characteristics, but are inserted here because of their being estimated from the rates given in Table A.

With definite knowledge as to the rate of progression of any given acid strength on a definite grade of copper or zinc, it will be possible to know the depth of etching after stated periods of time by simply observing the change in size of the black and white dots, after a

tion of rocking, brushing, etc., is in the line of greater scientific accuracy in result and an enlarged uniformity of quality. When this becomes every-day practice, then the chemical side of the process will have reached as great an accuracy as the present stage of the optical phases of the process.

Incidentally, it is interesting to note in the specimens from the same screen an absence of white dots in some of the deeper shadows, under the shortest time of etching, which are present in the engravings having had the greatest time in the etching bath. This would seem to indicate a variation in printing from the one negative. If at the end of the first period an electrotype was made and the etching continued on the same plate for the second period, and another electrotype made, and the etching again continued for the last period, and a third electrotype made, the succeeding interrelated stages would have eliminated therefrom any variable factor relating to the time of printing from the negative.

It is, of course, obvious that the sixty, forty and thirty-minute etches are overdone. In the high lights the dots have been "topped" and, in small areas, entirely destroyed. This is specially apparent when compared with the staged engravings shown in Fig. 4.

#### Broadening of Dots in Printing.

This is the *bête noir* of the inexperienced printer. From observations made on proof-press impressions of the specimens shown, there is an almost uniform widening of .0005 inch on each side of a dot, or an extension of this amount toward the white from the edge of any printing dot or surface. This materially reduces the tonal value and the brilliancy. From specimens used on daily papers, at sixty lines per inch, it was noted that the broadening due to soft paper, rapid presswork, stereotyping and inferior grades of ink was .002 inch in

meter of dot, as against .001 inch for the best ink, plated paper proving-press impressions. Overlays will have much to do toward rectifying this defect.

tion. When they are isolated it is difficult to notice the exact points where the broadening takes place, but when grouped it is apparent at once.

Fig. 3.—150-Line Flat Etch.

Fig. 4.—150-Line, Staged Etch.

Figs. 1, 2 and 3 show three period flat etchings made with 65, 110 and 150 line screens, at various durations of time in the etching bath, with acid of ordinary uniform strength.

Points of observation are marked on the staged engraving. Fig. 4—1, 2 and 3 for black dots, and 4 and 5 for white dots. The same points were used in each of the other specimens.

Tables C, D and E give the detail information of these specimens. Thanks are due to Mr. H. McRoy, superintendent of the Inland-Walton Engraving Company, for the preparation of the plates for Figs. 1, 2, 3 and 4.

TABLE C.  
ENGRAVING DATA OF WHITE AND BLACK DOTS, ILLUSTRATED IN  
FIG. 1—65-LINE SCREEN AT .0154-INCH PITCH.

	DIAMETER At end of 15 min.	DIAMETER At end of 30 min.	DIAMETER At end of 60 min.

White—Point 5 .....	.003	.0033	.0044

Fig. 6 illustrates a single-line electrotype from an "Akroton" engraving, which was produced automatically in a mechanical manner from a photo relief. It shows mechanical tonal analysis, through the medium of 65, 110, 130 and 150 lines per inch, produced with a V-shaped cutter of 90 degs. included angle. The photo relief presented a maximum variation of .0023 inch, which represents a part of

the depth of the engraved lines in the high lights; the remaining part is accounted for by the slight groove in the shadows, or "blacks" of about .0005 inch, making a total of .0028 inch.

The width of a groove in the high lights is twice the total depth, or .0056 inch, which, when subtracted from the pitch of a 150-line screen, .0066 inch, is equal to .001 inch, being the width of the ridge or printing surface between two parallel grooves. In this connection it is interesting to note the analysis of a recent print of one of Timothy Cole's wood engravings. In the nearest approach to "white"

Fig. 5.—Mechanical Engraving.

represented by single parallel lines at eighty-five per inch, the width of printing ridge is .003 inch. The pitch is .00675 inch and the ridges at this point represent 25.5 per cent. of unit area (1.85 by 1.85) as black.

The next tonal step toward "white" is found where the ridges are crosshatched, producing a square dot. At this point the lines per inch are ninety and the pitch is .011 inch. The black dots are .003

Fig. 6.—Mechanical Engraving.

inch square and comparable to unit area (1.90 by 1.90) represent 8.1 per cent. of it as black, the inverse being 91.9 per cent. white.

Daily newspaper publishers are using larger-sized engravings, so that the dots of .006 inch diameter in the high lights bear so much smaller proportion to unit area with coarse line screens than would the same size of dot to a finer line screen, consequently the percentage of white is greater in the case of coarse or few lines per inch than with many per inch.

In order to stand the mechanical strain of presswork and stereotyping without staged etching, it is not practicable to reduce the black dots much below .005 inch in diameter, hence the trend to coarser

lines; deeper etching and larger-sized subjects, so that individual dots bear a smaller proportion to the total number of dots used, consequently making them less noticeable.

The data herein set forth is not given as a finality, but is offered to half-tone workers as a contribution to the art, with the hope that it may draw out other observations along the lines of this most fascinating subject.

It is, of course, obvious that the deductions are based upon too small a number of observations to give absolute scientific stability to the conclusions drawn, yet it is believed, aside from possible errors, that enough has been pointed out to show to others how interesting and profitable to future workers investigations of this kind may be made, when researches are carried out more extensively.

N. S. AMSTUTZ.

## Exhibitions.

### HAMBURG AMATEUR PHOTOGRAPHIC SOCIETY.

AN exhibition of work by members of the Hamburg Amateur Photographic Society is being held in the Hamburg Art Gallery closing on Monday next, April 30. Altogether there are 152 exhibits, the largest exhibitors being Dr. Ed. Arning (president), Herr R. Dührkoop, Th. and O. Hofmeister, who contribute 21 prints; H. W. Müller, Robert Starck, and Bernhard Troch. The multi-colour prints shown by the Hofmeisters and Herr Müller are very striking by their harmonious effects, although monochrome prints in their neighbourhood suffer by juxtaposition to the brilliant colours. "Harzdorf," by H. W. Müller, is a beautiful rendering of a typical German scene, and it is difficult to realise the skill and labour which must have attended its production. The exhibition, however, is not by any means confined to gum. A number of prints are in carbon and platinum, and there are also some conspicuously good results on Velox and Matt albumen papers. In a short note in the catalogue Herr Theodor Hofmeister states the position of the photographic worker of multiple gum and his claim to be judged by what he produces. He says "Multi-colour gum printing has nothing in common with photography in natural colours or three-colour photography. Whilst in three-colour photography the colours are obtained by superposition of three positives in the fundamental colours—blue, yellow, and red—from three negatives, in gum printing the choice of colours is left to the printer, and only one negative is used. Hence there is much greater opportunity for the individual impression of the pictorial worker."

"It has been said that multicolour gum printing aimed at but did not attain natural effects, but the truth is that in multicolour gum-printing absolute truth to nature is not aimed at: the colours are so chosen that a purely decorative effect is obtained. This method of printing is merely a means for the pictorial worker to express colour effects and impressions, and has therefore a character of its own, so that a comparison with other media of making pictures, such as painting, etching, etc., cannot be made. Multiple gum-printing, as an absolute newcomer, must be measured by its own standard. It may be of interest to state that frequently fifteen or more printings are necessary to attain the desired effect. Tempera colours are exclusively used, and it is important to note that only those are chosen which are stable to light and air. As there are no chemicals in the pictures, the latter represent an absolutely hard, permanent film of colour and gum. Bleaching of the colours or other changes in the prints is therefore excluded. Duplicate prints, on account of the complication of the printing, are only possible in the way a painter might repeat his work. It is quite possible, however, for the expert to obtain several pictures differing in feeling and colour from the one negative."

### BOLTON AMATEUR PHOTOGRAPHIC SOCIETY.

THIS society's exhibition was held on April 18, 19, and 21 in the Victoria Hall, Bolton, and proved an unqualified success. It was opened on the first day by Alderman Wm. Nicholson, J.P., the chair being occupied by Ed. Blackburn, Esq., J.P. Many outside workers having taken advantage of the arrangements made with the committee of the Northern Photographic Exhibition for the forwarding on to Manchester of pictures destined for that exhibi-

n, the open class was very well represented. The members' class, while hardly so large as might be expected from a society with so large a membership roll, showed a marked advance in quality on previous years, the novices' class in particular including some very creditable exhibits. The judges were Messrs. C. F. Inston, R.P.S., and A. A. Bellingham, and their awards were as follows. Section 1, open classes—Class A (landscape, seascape, and river scenery): silver, F. Judge; bronze, H. A. Blades. Class B (portraiture, figure, and animal studies, and still life): silver, Miss H. Stevenson and E. Seymour; bronze, W. Duxbury. Class C (architecture): silver, J. P. Howe; bronze, S. C. Stean. Class D (lantern slides): silver, E. Seymour; bronze, H. Wormleighton. Section 2, members' classes—Gold medal (presented by Jas. Lord, Esq., for the best picture in Section 2), H. S. Prince. Class E (any subject, pictorial or technical): silver, H. Mills; bronze, W. Midgley and J. M. B. Stubbs. Class F (lantern slides): silver, M. B. Stubbs; bronze, J. Pilkington. Class G (any subject for members not having previously taken any award): silver, T. W. Cross; bronze, T. Shaw. Apart from all financial consideration, the exhibition's value as stimulant of the pursuit of photography in Bolton and district unquestionable, and the joint exhibition secretaries, Messrs. W. Midgley and H. M. Kellam, are to be congratulated on the result of their efforts.

# CHEMISTS' TRADES.

THE twelfth exhibition organised by the "British and Colonial Druggist" was opened in the Royal Horticultural Hall, Vincent Square, Westminster, on Monday last, and closes to-day (Friday) at 10 p.m. The large hall is chiefly filled with the stalls of the wholesale drug firms, and the enterprise of these trades' representatives proves at times a little disconcerting to the non-chemical visitor. One is unprepared to be the recipient of bursts of confidence from immaculately frock-coated gentlemen who address one in a stage-whisper such inquiries as "Are you interested in castor oil?" or "Can I show you this new tooth-brush?" We hasten to seek out the photographic stalls in the exhibition and discover Messrs. Houghtons, Limited, making a large show of their well-known apparatus, with the addition to the series of hard-index negative files of one very neat numerical series of card-envelopes for film negatives, in which the film is kept flat, and is instantly removable from, and replaced among, its fellows. The Rotary Photographic Company, Limited, divide their space among three-colour carbons, paper negatives, and prints on "Silvo," alk. (bromide emulsion), and their new collodion paper.

Mr. J. E. Lockyer exhibit a great variety of amateurs' chemical specialties. Messrs. Chas. Zimmermann and Co. show all things "Agfa," and some very striking prints on collodion papers used in their combined gold-platinum bath, a procedure which, as they take the opportunity of emphasising, is in every way as simple and reliable as the self-toning papers. They also show a very neat pocket-folding camera, of Ernemann's. Mounts and cameras in many patterns are exhibited by Chas. Tyler and Engstrom Bros., who, with the four firms we have noticed, make up the photographic exhibitors. Yet the exhibition is one where a pleasant hour may be spent amid brilliant, and, we may add, seductive surroundings, and within sound of the strains of a very excellent orchestra discoursing popular music.

OWING to great pressure on our space this week, a number of articles, including that on "The Use of the Spectroscope," by Mr. Wall, "A Note on the Motion of the Pendulum," and others, are held over until the next issue.

The report of the Stackman v. Paton copyright case must also stand over until next week.

THE Kodak Company have arranged to give at their gallery, 115, Oxford Street, each afternoon, between 3.30 and 4.30 (Saturdays excepted), a free, interesting, and comprehensive explanation and demonstration of the whole simple system of Kodak daylight photography, from start to finish—taking the picture, developing the negative in daylight, and making the finished prints. This information is imparted in the brightest and most interesting way, choice results taken with the various Kodaks being shown by the lantern screen.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between April 9 and 14:—

EXPOSING RECEPTACLES.—No. 8,522. Improved method and apparatus for transferring photographic layer-carriers from an exposing chamber to a receptacle located under the same. Optische Anstalt. C. P. Goerz Akt. Ges. 51, Bedford Street, Strand, London.

CAMERAS.—No. 8,788. Improvements in photographic cameras. Bertram George Cooper, 36, Clarence Street, Kingston-on-Thames.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

LANERN DESIGNS.—No. 14,527, 1905. The claim is for the combination with a magic-lantern (provided with a stationary or slowly rotated transparent slide coated on one side with soot or other opaque covering) of a graving-point arranged in connection with and operated by two rods oscillated at right angles to each other through the medium of cranks mounted on separate spindles, one of which is driven direct, while the other receives its motion from the said driven spindle by means of interchangeable pulleys or wheels, together with means for automatically moving the crank-fittings carrying the oscillating rods inward or outward on their cranks. Andrew Forbes, 136, Otley Road, Leeds.

EXPOSING DEVICES.—No. 10,956, 1905. The apparatus comprises in suitable combination three working parts, one adapted to move so as to allow a packet consisting of two envelopes sliding one

Fig. 1.

Fig. 2.

Fig. 3.

within the other (the inner one holding the plate or film) to be slid into proper position in the dark slide, another to ensure the correct placing of the film in the plane of the focus of the camera lens, and to hold it in such plane when the envelopes are being and have been withdrawn, and the third adapted to slide so as to open the magazine to allow the exposed film or paper to enter thereto, and to close the magazine again in light-tight manner. Referring to figs. 1—6, the magazine E is held by spring pressure against a frame D, from which it can be moved away to form slits i and k for the purpose of inserting the packet shown in fig. 1 into the position shown in fig. 2, in which position it rests against the slide F that forms the face of the magazine. In this position the packet is pressed upon by a frame G mounted within frame D, and urged towards the slide F by springs h. Strips of velvet l make a light-tight closure between the frame D and the walls of the magazine E. The film C has two perforations e at the edge, which is to the left hand in the figs., and the inner

envelope A is cut away to leave these perforations uncovered when the outer envelope B has been withdrawn through the slit *k*. As soon as this has happened two pins *m* fixed to a plate *a* urged forward by springs *d* interposed between the said plate and the sliding bottom *r* of the magazine enter the perforations *e* as shown in fig. 3. It is now possible to withdraw envelope A through the slit *i* without shifting the film C, which is then immediately pressed by the spring frame G and held thereby against the slide F ready for exposure. After exposure the film is to be transferred to the magazine. For this purpose the slide F is withdrawn until the projection *c* on its left hand

Fig. 4.

Fig. 5.

Fig. 6.

edge catches against the side of the magazine. The frame G has its right-hand side bevelled or sloping as at *s*, and at a short distance from its opposite side it is connected by slots and pins *G*<sup>1</sup> with the frame D. Hence when the slide F is withdrawn the bevelled side *s* of the frame G falls until it rests on the edge of the slide as shown in fig. 4, bringing with it the film C. The slide F is now returned, and in its inward movement slides against the bevelled side *s* and lifts the frame G back to its former position. At the same time the slide engages the film C (fig. 5), and causes it to travel down the pins *m* until it rests on the plate *a*, or on the films already in the magazine. In order that the film may not be damaged by the edge of the slide, the latter carries two rollers *o*, *p*, over which passes a band *q*, the ends whereof are clamped by a plate *b*<sup>1</sup> in the side of the magazine E by screws *b*. These screws also serve as an abutment for a fillet *f* on the edge of the plate *a* to prevent the latter from being moved too far by the springs *d*. The exposed films are removed for development by withdrawing the bottom *r* and taking out the plate *a*. Oscar Becker, 62, Jerusalemstrasse, Berlin, S.W. 19.

#### CATALOGUES AND TRADE NOTICES.

Messrs. Morley and Cooper, 271, Upper Street, Islington, London, in sending us a catalogue of cameras for the season, remind us of the special feature which they make of all classes of repairs to photographic apparatus. It is frequently a convenience to know of a reliable house to which an erratic shutter or damaged camera may be sent for restoration, and Messrs. Morley and Cooper may therefore reasonably claim the custom of photographers in this direction, and for the building of all classes of photographic and lantern apparatus to specification.

The new illustrated catalogue of Messrs. Lizars, Buchanan Street, Glasgow, is at once a comprehensive list of amateurs' requisites, and a compendium of formulæ and tables, and notes, which conveys a good deal of practical information. The list, which runs to 200 pages, is obtainable for a penny stamp.

The "Imperial Handbook" for 1906 reaches our table from the Imperial Dry Plate Company, Limited, Cricklewood, specifying, as usual the manufactures of the company, but providing also a variety of very practical advice, which may be studied with profit by users of any brands of plates and papers. In addition to containing the formulæ for the various developers recommended by the Company and a table for development by time, it offers some technical articles

on the choice of developers, on outdoor and indoor photography, on defects in negatives, hand-camera work, home portraiture, and backed plates. Altogether a budget of valuable reading, which will tempt the amateur worker to apply to the Company for the copy which is offered post free.

## New Apparatus, &c.

The Mackenzie-Wishart Daylight Slide. Made by Mackenzie and Co., 17, Douglas Street, Glasgow.

Whatever may be urged in favour of devices for changing plates such as those which form an inherent part of hand-cameras or are sold as separate changing boxes, there are many who, with good reason, pin their faith to dark slides as the only method of carrying plates or films which can be trusted to work without a hitch. The lapse of a changing mechanism from the path of rectitude may be rare, but is none the less annoying and embarrassing when it does transpire, hence the very natural preference of those who have suffered to fight shy of all sorts and conditions of mechanism for the carriage and exposure of their plates. Yet this opposition can hardly be extended to apparatus of the class of the Mackenzie-

Fig. 1.

Fig. 2.

Fig. 3.

Wishart dark-slide, which is certainly innocent of working parts of greater degree of complication than an ordinary dark slide, and possesses the very great advantage over the dark slide that it reduces the bulk and weight of the apparatus needed to carry a number of plates by a degree which is greater the more plates there are, and permits the photographer to take a very considerable number of plates into the field for a moderate outlay. We noticed the Mackenzie-Wishart apparatus on its first inception, and it is now our duty to revert to it in order to chronicle improvements in it, and the introduction of a pattern specially designed for the amateur worker. Each plate, we may say to those who do not know the apparatus, is carried in a light flexible envelope slide, consisting of three parts (Fig. 2), an outer sheath, an inner one holding the plate, and a shutter working in a groove formed by the two. In the apparatus as originally made, it was not the easiest matter to insert the plate in its carrier, but greater rigidity of the latter has removed this difficulty, and we can say as the result of working at frequent intervals for more than a year past with the apparatus, that we have

and it reliable in the field both as regards safety of the plates in light, and uniformity in performance. The advantage in diminished weight and bulk is an obvious one to anyone who examines—Messrs. Mackenzie send on approval—a slide and envelope. The system should appeal to the professional photographer for the facility by which he can quickly be equipped with as many plates as unforeseen emergency may demand that he take into the field with him. We are informed that one firm possesses 150 envelopes

Fig. 4.

for use in one or other of two slides. The new slide is shown in the fourth figure, from which it will be seen that the envelope has a rigid ebonite shutter, which pulls completely out, the pile surface of the slide back and the plate carrier forming an efficient light trap. The complete slide in quarter-plate measures 6 x 4½ x ¾ inches, and costs 8s. We believe it is made also in half and whole-plate sizes at prices which, with other particulars, Messrs. Mackenzie will supply.

We are now able to give a drawing of the new dish of Messrs. Tunnell, which we were able to review favourably last week. It has been suggested that the dish permits of two plates

being developed or fixed at one time in a single dish, but we cannot suppose that such a proposition would be seriously considered by a photographer except under very restricted conditions of time and space.

AN exhibition of photographs by Alvin Langdon Coburn opens at the rooms of the Liverpool Amateur Photographic Association on May 1. The private view is on Monday next, April 30. A special feature of the exhibition will be a series of recent pictures of Liverpool.

THURSDAY Evenings at the Blenheim Club.—The following are the fixtures for the next two Thursday evenings:—May 3, smoking concert, Mr. E. J. Humphrey in the chair; May 10, Messrs. A. J. Hubbard, M.D., and George Hubbard, F.S.A.; "Dew Ponds: Ancient and Modern," the Earl of Rosse in the chair.

A KEIGHLEY One-Man Show at Keighley.—An exhibition of the pictorial photographs of Mr. Alex. Keighley was opened last week in the Art Gallery of the Carnegie Library, Keighley. The pictures, by Mr. Keighley's permission, have been recently exhibited in the Cartwright Hall, Bradford, and at the Corporation Art Gallery, Burnley, and their tour is now appropriately brought to a conclusion by an exhibition for the benefit and interest of Mr. Keighley's fellow-townsmen. The collection, which has been admirably and tastefully arranged, includes all Mr. Keighley's recent works, many of which have become classical in photographic circles. It will remain on view until Whitsuntide.

THE Alhambra has just secured an admirable series of photographic views of San Francisco, taken only a few days before the earthquake. These striking pictures will be included in the Urbanora exhibit every evening at ten o'clock.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
27.....	Aberdeen Amat. Photo. Assn.	Resumé of Season's Work. Mr. Gray.

2.....	Edinburgh Photo. Society	"The Proper Sphere of Photography." Illustrated. Mr. Alex. Sutherland.
2.....	Everton Camera Club.....	"Composition." Mr. G. Taylor.
3.....	Tunbridge Wells Ama. Ph. Assn.	"Some Irish Holidays." Mr. A. W. Punnett.
3.....	Cardiff Windsor Amat. Ph. Soc	Opening of Members' Exhibition.
3.....	London and Prov. Photo. Assn.	"Funnies Heard at the Dealers Counter." Mr. Ernest Human.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at 51, Baker Street, W., on Friday, April 20. Present: Messrs. F. A. Bridge, Alfred Ellis, S. H. Fry, William Grove, E. H. Hall, P. Lankester (Tunbridge Wells), A. Mackie, D. Prodger, Edgar Scamell, Lang Sims, and R. Fellows Willson.

Letters were read from Messrs. G. P. Abraham (Keswick) and T. Rowe (Eastbourne) thanking the committee for their election.

Mr. William Grove was re-elected hon. secretary and treasurer. A discussion took place upon a suggestion of the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY that, following the lines of the recent exhibition of work of the Professional Photographers' Association of America, the Association should undertake to organise a similar exhibition, each member to be invited to contribute one work, the exhibition to be held at the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY. It was finally decided to carry out the suggestion, and that a circular be issued to members inviting each to contribute an unframed picture typical of his style of work, the outside size of mount not to exceed 12 x 10 inches, or 120 square inches.

A letter was read from the Actors' Association inviting the committee to receive a deputation from that body to discuss questions of copyright in photographs of members of the dramatic profession. It was decided to invite the deputation to meet the committee on the date of and previous to the next committee meeting. The committee authorised the removal from the list of members of all those who had not paid last year's subscriptions. Attention was called to an important decision on photographic copyright, referred to in the current number of THE BRITISH JOURNAL OF PHOTOGRAPHY, but discussion upon it was deferred until a report of the trial was available.

Mr. Lang Sims brought forward the question of invitation and free sittings, and it was pointed out that in the present state of copyright law, under which, to obtain copyright in the photograph, the photographer is obliged to take the negative without receiving valuable consideration, it was impossible to deal in any satisfactory way with the matter.

THE first open exhibition of the recently formed Photographic Association for Crief and District was opened in the Porteous Hall last week. There was a large and interesting collection of pictures, including some fine examples of seascape and river scenery.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held April 24, the president, Major-General Waterhouse, in the chair. A paper by Mr. W. A. Scoble was read by the Secretary on the "Red Sensitiveness of Dyed Films," which detailed his experiences in photographing the infra red lines of certain arc spectra. A concave diffraction grating was used with a curved film, and as a check also a two-prism spectroscope with a flat film, a 100-volt Nernst lamp being used as a source of light for the two. The spectrum was photographed in two sections, the violet up to the orange, and thence into the infra red. Comparative curves of the sensitising action in this region were shown of all the new isocyanines, together with alizarine blue S which was found to give the greatest speed and greatest red sensitiveness, extending to wave-length 8,700 about. The great disadvantage of this dye was that the solution would not keep and the sensitising action was uncertain, even with freshly prepared dye. The final method adopted for the preparation of the dyeing solution was to dissolve one part of alizarine blue S, in 500 parts of alcohol with ten parts of ammonia, and then add 500 parts of water; the solution thus made must be carefully filtered and used as soon as possible.

Mr. C. E. K. Mees was interested to note that Mr. Scoble, like other workers, had come to the conclusion that the best red sensitiser was pinacyanol. Mr. Scoble's experience of alizarine blue S appeared to be exceptional, as no one seemed to have used the dye with any success except Mr. George Higgs, and even Mr. Scoble had to admit that it was erratic, and gave only a small proportion of good results. Mr. Mees criticised adversely the curves given Mr. Scoble for sensitiveness, saying that they were not from measurements. He deprecated the publication of guessed curves as a frequent means of spreading errors in photographic techniques.

Mr. S. E. Sheppard suggested that workers on the sensitising properties of new dyes should pay attention to recent work on pseudo-solution and the colloidal state as likely to throw light on many discrepancies.

Mr. A. J. Newton could not agree with Mr. Scoble in his experience of dicyanine, which did not possess the gaps in the green alluded to in the paper. However, the dye was too slow to be of any practical use.

Mr. C. P. Butler, referring to the different experiences with alizarine blue, suggested that the cause lay in the dilution of the dye and the use of ammonia. He thought that an examination of these two factors would lead to greater constancy of result.

The Chairman said that attention should also be given to the purity of the ammonia; the behaviour of an impure sample with the dye was quite different.

A paper by Drs. J. H. Smith and Merckens, of Zurich, was then read by Dr. J. H. Smith. It dealt with a new tissue or paper for the printing of natural colours in one operation by the bleach-out process. Dr. Smith said that the recent exhibition of colour photography at THE BRITISH JOURNAL OF PHOTOGRAPHY had shown the very widespread interest taken by the public in the subject, and had also demonstrated the difficulties in the way of the regular practice of three-colour work. It might be possible for a professional photographer to take up such work with success, but the processes at present available were beyond the powers of the average amateur. The Lumière starch-grain method was a step in the desired direction, and he (Dr. Smith) some years ago worked out a somewhat similar process, in which, however, instead of an irregular grain, he employed a geometrical arrangement of filter made in hexagons which completely filled the plate like the cells of an honeycomb. He had lately found means of putting this method into practice, and he hoped to have it at the disposal of photographers before very long. As regards printing processes, however, the bleach-out method, by its great simplicity, was quite ideal. In the past it had not been very successful. Neuhaus and Wörel had not achieved much success with it. In conjunction with Szecepanik, the lecturer had made a bleach-out tissue with separate films, but the authors had now worked out a new method of preparing a tissue at one coating, which gave greatly improved results. They had also invented new dyes which permitted of a more sensitive and permanent tissue. The exposure of the tissue was made in two stages, during the second the tissue being backed with blotting paper containing peroxide of hydrogen. This

ensured the complete bleaching of the red dye. A number of results on the new tissue were exhibited and examined with interest by those present.

A short discussion followed, in which Messrs. E. J. Wall, H. Maclean, E. T. Butler, and W. Gamble took part.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION. — On Thursday, the 19th, Mr. L. Thornton, the inventor of the new Mattos printing paper, lectured upon and demonstrated that paper. He said that from that day they were introducing further brands of the paper, and as his idea had been all along to use only English-made paper as a base, the whole of the ten grades were of home manufacture except one, No. 5, which was French, this one being of an exceedingly fine surface. The paper was now obtainable in white, cream, buff, and French grey, and, with the exception of the one already named, the raw papers were made by Whatman and Hollingsworth. The paper was as pure as it was possible to make it, being made of specially picked rags of very long fibre, and sized with pure gelatine, and he claimed to be the first maker of photographic papers which were pure English throughout. As at present issued, there was not any bronzing in the printing, and there was very little loss of depth in the toning, most workers, in fact, when first using these papers were apt to overprint. In connection with this fact, Mr. Teape (the chairman) said that he had that evening put out to print a sheet of the paper at 5 o'clock, and had the finished result by ten minutes to seven. A large number of untuned prints were here passed round, and surprise was expressed at the depth of printing, it being generally thought that they were not carried deep enough. They were, however, followed by a series from the same negatives, printed to the same depth and toned, which undoubtedly showed that the printing given had been quite sufficient to give a good print and of very soft nature, and in connection with this Mr. Thornton warned members against over-toning. For the gold and platinum bath he preferred to mix the two salts together, and said a bath so made would keep indefinitely. Salt was added to the bath because he did not wash the prints before toning, and he thought that to kill the free acid in the paper by this method, together with soda carbonate in the fixing bath, was better than washing. The following gold bath gave beautiful rich brown tones, and it would be noticed that it contained a large excess of borax:

Stock solution A:	Borax .....	180 grains.
	Soda acetate .....	180 grains.
	Citric acid .....	15 grains.
	Water .....	35 ounces.
Solution B:	Gold chloride .....	15 grains.
	Water .....	35 ounces.

Keep in separate bottles, and mix ten parts of A with two parts of B just before use. Mr. Thornton, however, greatly preferred the gold-platinum bath as follows:—

	Salt .....	45 grains.
	Citric acid .....	90 grains.
	Potass chloroplatinite .....	15 grains.
	Water .....	20 ounces.

To this was added 1oz. of the gold stock solution above. Tone and fix in

	Hypo .....	20 per cent.
	Soda carbonate .....	2 per cent.

By first plunging the prints into a 1 in 20 solution of ammonia and then toning in the gold bath, the prints would slowly tone to a pure sepia, and would not go beyond this shade of brown. Prints of old paintings were here passed round, and the nature of the paper base, together with the peculiar brown shade that had been obtained, made them scarcely to be distinguished from old engravings. By fixing alone good browns could be obtained, whilst a mixture of ammonia and hypo gave a beautiful brown tone very suitable for pictorial work and portraits. The older the paper was the better it worked and the better the tones. He never, if it was avoidable, used paper less than four weeks old. The papers were of what was known as the salted class. The chairman and Mr. Ernest Human passed round prints on the paper, Mr. Human remarking that from what he had seen and heard during the evening he had come to the conclusion that he had rather over-printed. Mr. Thornton, however, said that to his mind the prints were very fine, at the same time complimenting Mr. Human on his nega-

Mr. Hector Maclean, in proposing a vote of thanks to Mr. Thornton, said he wished personally to express his great approval of the beautiful range of tones obtained upon the paper, and he thought that they were of such a nature which would, he was sure, confer a great benefit upon the professional photographer who would only try the paper. Whilst the professional had such paper at his disposal, it was, he was sure, very unwise not to experiment with it, as he was certain that it would mean both more business and be money to them in the long run. Mr. Freshwater, in seconding, said the association were much indebted to Mr. Thornton, and he thought that the beautiful results were far ahead of any other printing-out process at present known. The chairman agreed fully with all that had been said, and added, at his opinion the paper was, without doubt, one of the best he had tried, and he was greatly surprised at the ease with which work was worked.

## Correspondence.

- \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
\* We do not undertake responsibility for the opinions expressed by our correspondents.

### BLEACHING BROMIDES.

To the Editors.

Gentlemen,—With reference to your reply, April 20, 1906, to R.D., on Toning of Bromides, having experienced the same difficulty myself, I should like to offer my explanation of the matter if you will allow me.

The formulæ I use is as follows:

A. Potassium ferricyanide .....	100 grains.
Potassium bromide .....	100 grains.
Water .....	10 ounces.
B. Sodium sulphide .....	50 grains.
Water .....	10 ounces.

Determined to find the reason of prints bleaching but failing to appear when put in sulphide solution, I made a little experiment, printed, developed, and fixed, six prints from one negative, same exposure, etc., for each. I then gave them half an hour's washing. Three prints I put direct, without drying, into the bleaching solution. The other three I put to dry. The three that were put in the solutions without drying, bleached all right, but when put in the sulphide solution failed to re-appear. The other three prints, when thoroughly dry, were put into the bleaching solution, washed, and then put into the sulphide solution. These three came up grand. I therefore came to the conclusion that the prints must be washed and dried before toning.—Yours respectfully, J. ALLEN.

39, Cynthia Road, Bath.

April 21, 1906.

### THREE-COLOUR PORTRAITURE.

To the Editors.

Gentlemen,—It may interest both you and your readers to know that I have obtained perfect results during the present month in the studio with an exposure of 10 seconds (inclusive), lens working at f/3.5.—Faithfully yours,

R. BECKETT AND SON.

The Grove, Hackney, London, N.E., April 24, 1906.

### NEW COMPANIES.

MAYALL and Company, Limited.—Capital, £2,000, in £1 shares. Objects: To acquire the business carried on at 126, Piccadilly, W., as Mayall and Company, Limited; to adopt agreements (1) with Lucy M. Barraud, and (2) with Lucy M. Barraud, A. Parkes, C. H. Barraud, and W. P. Parkes, and to carry on the business of photographers, photographic artists, etc. No initial public issue. The first directors (to number not less than two nor more than four) are: A. Parkes (managing director), C. H. Barraud, and W. P. Parkes. Qualification, 100 shares. Remuneration, 5 per cent. of the net profits divisible. Registered office, 126, Piccadilly, W.

## News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—The lecture which was to be read by General Waterhouse on May 8 has been postponed, and a paper, entitled "A New Formula for Expressing Density in Terms of Exposure," by Mr. H. J. Channon, will be read in place of it.

The exhibition of work of the Birmingham Society will be opened at the premises of the Royal Photographic Society on Monday next at 8 o'clock, when an address prepared by Mr. Harold Baker will be read by Mr. P. Bale Rider.

PHOTOGRAPHY in Charity.—Always ready to assist in any charitable cause, the members of the Norwich Ladies' Camera Club have arranged an exhibition and series of entertainments on behalf of the Jenny Lind Infirmary for Children, and the inaugural ceremony took place on April 19 in the Thatched Assembly Rooms. The exhibits consist of two hundred excellent photographs, which, with one or two exceptions, will be sold and the proceeds devoted to charity. The photographs, which were artistically hung along the walls beneath the windows, were non-competitive, and included many subjects. All were excellently finished, and of a very high standard. Particularly noteworthy was a series of views from the Nile, taken by Miss Edith Willis and Mrs. Willis, the club secretary; while Miss Edith Willis also included an interesting series of photographs from Oberammergau. Some admirable views of Swiss scenery were exhibited by Miss Mary Willis, Miss A. Mace, and Mrs. Mottram. Other exhibitors included Miss Alice H. Brown, Miss Ethel Coleman, Mrs. E. T. Boardman, Miss Katie Chamberlain, Miss Emma L. Boardman, Miss Nancy Gibson, Miss Dorothy and Miss Violet Hotblack, and Miss Mary Cozens-Hardy, the subjects ranging from architecture to Broadland scenes. Although the photographic display is alone well worth a visit, the promoters felt that some other form of entertainment should be arranged for the benefit of those who were not keenly interested in the art, and, with the co-operation of a number of ladies and gentlemen of musical and dramatic taste and talent, some capital concerts and theatrical performances have been organised.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.  
\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.  
\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.  
\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

J. Jarrett, Ewart Lodge, Jamoson Road, Bexhill, Sussex. Two Photographs of the Official Inauguration of the Bexhill Electric Trams.

A. McGregor & Sons, 48, King Street, Kilmarnock. Three Photographs of Dr. A. Rolland Rainy, M.P.

E. A. Basevi, 38, Hills Road, Cambridge. Photograph of the Rev. E. H. Benson

TREATING Prints.—I shall be glad if you can inform me of any method whereby P.O.P. prints can be treated so as to make it difficult for them to be reproduced. I have not much confidence in the lay Press when it refers to photographic processes. I enclose you a cutting that has prompted me to trouble you. I shall look for your reply in "Answers to Correspondents."—JEWDRISHUS.

It has been stated that if a name or word be written across the print with a strong solution of sulphate of quinine in acidulated water that it will show when photographed, but in our experience such is not the case with gelatine plates, although it may serve in the case of wet collodion. We think the paragraph is a relic from the fifties and sixties of the last century.

FINGER PRINTS.—I have become very interested in obtaining photographs of finger prints. I should like to know what powder

is used in bringing out the image on an article, and how it is transferred to a paper and then photographed. Is there any book on the subject, and where obtained; if not, could you instruct me in any way.—B. R. J.

We have had no experience in this work, and can only suggest that the impression should be intensified by dusting some impalpable powder, such as bitumen, over it. The surplus having been dusted off, that adhering to the impression could be fixed by heat. In the case of finger prints being made, we may quote from Dr. Francis Galton's directions as follows: Ink a piece of glass plate with printer's ink by means of a printer's roller, applying the ink very uniformly and thinly. The coat of ink should be so thin that when the inked plate is held between the eye and the light its tint should be of a smoky yellow, very far from black. Press the finger first on this inked glass and then on a porcelain palette, such as is used by painters in water colours. The extreme whiteness of the palette contrasts well with the impression upon it, and makes photography easy.

**QUICK CHANGE.**—We should say the market value of the apparatus is very small. You might dispose of it to a seaside firm or travelling photographer.

**PLATINUM.**—1. Could you kindly let me know if matt albumen paper toned in platinum bath *alone* is permanent? Bath used is potass chloroplatinate and phosphoric acid. 2. Also what is the cause of grainy sepia platinum prints? Is it due to paper getting too dry or thin negatives, even if printed in subdued light? I use developer at proper heat, 150-160 deg. Would chalky water cause it?—E. P. L.

1. The results should be perfectly permanent if the usual precautions for platinum toning are observed, chiefly ample washing between toning and fixing. 2. Too cold a developer is the most usual cause. A water containing lime is not likely to give rise to trouble if the precipitate which is produced by the oxalate is allowed to settle.

**RELIEF NEGATIVE.**—Some years ago I saw a small fine plaster medallion cast from a special photographic negative of a man's head and bust in beautiful relief. May I ask if you know of a business firm who produce such medallions or who will produce the deeply relieved negative from which they can be cast?—F. BEWLEY, 24, Bewley Street, York.

Several methods of producing reliefs have been brought, but none which is photographic throughout. Messrs. Marion, we believe, still supply prints in relief, but perhaps some of our readers can reply to our correspondent's specific question.

**THE BLEACH-OUT COLOUR PROCESS.**—In the number of April 13 of THE BRITISH JOURNAL OF PHOTOGRAPHY, page 282, I see that Drs. Smith and Merckens, of Zurich, have discovered a process for printing coloured photographs, and you speak of bleach process. Would you be kind enough to say to your readers in what the bleach process consists?—READER AT BRUSSELS.

See the report of the Royal Photographic Society's meeting on another page.

**RETOUCHING (Reply to H. F.).**—Your work is fair considering the extent of your experience, and in time you should become a good retoucher. In every case prints before and after retouching should be sent, otherwise it is impossible to judge how the character and likeness have been retained. Your large head is the best of the series, but be careful not to pinch the corners of the mouth, and also see that the heavy shadows round the eyes are considerably lightened, when excessive, as in this case. Your touch on the two other samples sent is too equal in pressure and insufficiently blended, and, therefore, spotty in effect.

**CLOUD BACKGROUNDS.**—I shall be glad of information through your correspondence as to the following:—What dyes or chemical preparation are used for making cloud backgrounds? What I have seen used has been of a purplish shade, producing deep shadows and soft graduation, and applied with a brush as used for cleaning boots.—ERNEST F. USHERWOOD.

Mix together whiting and lampblack to the shade desired, and then add to the mixture about a third of its weight of dextrine strain unbleached calico on the frame, and make thoroughly wet. Lay the frame on the floor and dust the mixture over, and well work into the fabric with a clothes or

shoe brush. By making two mixtures, one containing more black than the other, they may be blended with the brush so as to produce good clouds. In place of the whiting and lampblack any dry colours may be used.

**STAINING STUDIO FLOOR.**—1. I am about to furnish a new studio, and want the floor done with a centrepiece with the wood stained a nice dark colour, forming a broad border round the studio. Could you give me a receipt for a cheap, easy made stain? I think I remember of you giving one in the JOURNAL a couple of years ago. I think it was simply an acid or some chemical in water to stain a dark walnut colour. If you can give this would you kindly say it it would be best to be varnished or polished after staining? 2. Would a piece of red felt do for centre of floor, as I do not want an expensive carpet, or would linoleum be better with the dark stained border?—"STAIN."

A good stain for the purpose is:—Brown hard varnish,  $\frac{1}{2}$  gallon; methylated spirit,  $\frac{1}{2}$  gallon; burnt timber in powder, 1 lb.; burnt sienna, 1 lb.; and lampblack, 2oz. to a quarter of a pint, according to the shade desired. Mix thoroughly. After applying it is better to varnish. Wood stains are to be purchased at most oilshops, and are very cheap. A useful little book, price 6d., is published in the "Useful Arts and Handicrafts" series, or "Dyes, Stains, Varnishes, Etc.," Dawbarn and Ward, Farringdon Avenue. The number in the series is four. You will do well to get it. 2. We should prefer linoleum, in preference to felt, for the centre, because on that the camera stand would travel much better than on the looser fabric.

**GELATINO Chloride Paper.**—I have been trying to coat small quantities of P.O.P., and after floating the sheets on the sensitising tray I notice numerous small, bright points showing like specks of silver on the faces of the coated sheets. Some of these apparently dry out, but some larger specks remain. Could you kindly enlighten me as to what they really are, and give me a remedy? Looking at the sheets immediately after cooling in front, the specks are not noticeable, but upon holding up to gaslight at an angle they appear like bright points upon the face of the paper, the sheets with this exception being perfectly clear.—BARYTA.

This defect is due, we believe, to minute air bubbles, which are either in the emulsion or cling to the surface of the baryta paper, and when the paper is lifted off they rise to the surface, but cannot escape, because the gelatine has set there. If the emulsion is allowed to stand some little time before the paper is floated and the surface skimmed, we think this trouble may be got over.

**H. HARRISON.**—The terms mentioned on p. 676 of the "Almanac" apply in the case of a sitting where the copyright is to remain with the photographer.

**RETOUCHING (reply to E. M.).**—Very good, yet open to improvement. For this paper and subject a bolder and softer grain would give a more effective result and overcome the general hardness of the working. The high light on cheek is too much like a lamp ray on a dark road, and should be better diffused. The lighting by face line gives a rather swollen appearance to the cheek, and the chin calls for nicer modelling. With care and attention to every detail there is no reason why you should not become a first-class retoucher.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

natural backgrounds in portraits taken in the studio. A most  
nious process by which any background is combined, in  
ect registration, with a portrait made in the studio, has been  
ked out by a Swiss inventor, Herr Dischner. Only one plate  
sed in obtaining the composite negative. (P. 346.)

t the Northern Exhibition at Manchester the two first awards  
e fallen to Mr. R. Dührkoop, the second going to the picture  
"Twilight," reproduced last week in illustration of the exhibition  
Dührkoop's work now being held at these offices. (P. 351.)

he copyright case of Stackemann v. Paton, recently heard in  
High Court, puts a new construction on the term "good or  
able consideration." Mr. Justice Farwell held that certain  
essions to the photographer may be "good consideration."  
(P. 343.)

Ve regret to announce the death of Mr. William Grove. (P. 345.)

Ve give the report of the discussions at the Convention of the  
S. of New York on free sittings and school rates, etc. (P. 347.)

fr. Pennell at the Society of Arts last week was good enough  
say that "all artists were agreed that three-colour work had  
ays been rubbish and always would be." (P. 342.)

achine for reproducing the tones of a photograph in straight  
s is among the patents of the week. (P. 353.)

ow to use a pendulum for measuring shutter speeds. (P. 350.)

## EX CATHEDRA.

### Mr. Dührkoop at Manchester.

We have to congratulate Mr. Rudolf  
Dührkoop on securing the first two  
awards at the Northern Exhibition at  
Manchester. The first goes to a picture which we do  
not recognise by its title, but the second falls to the indoor  
portrait study of "Dämmerung," or "Twilight," which we  
reproduced last week by way of providing a souvenir  
of the present exhibition of Mr. Dührkoop's work which  
we are holding at these offices. By one of those fortunate  
chances which seldom fall in the path of the technical  
journalist, the copies of THE BRITISH JOURNAL OF PHOTO-  
GRAPHY containing this reproduction arrived in Manchester  
a few hours before the judging. We are afraid we cannot  
lay the flattering unction to our breasts that the incident  
was a specimen of what Lord Curzon calls "intelligent  
anticipation of events before they occur," but we have had  
the satisfaction of knowing that Manchester was able to  
turn to its B.J. for a review of Dührkoop's work and some  
particulars of the man at least ten days before any other  
photographic paper could print a line upon these topics.  
We may add to the notices which have already appeared of  
the Dührkoop Exhibition at our offices that even apart  
from the photographs, the selection of mounting papers  
employed by Mr. Dührkoop have been considered by some  
visitors as deserving of a close study. It may also interest  
our readers who have visited the Exhibition to know that  
the Hamburg Corporation have awarded a gold medal to  
Dührkoop for his collection of portraits, "Men and Women  
of Hamburg in the Twentieth Century." The issue of  
"Das Atelier" which makes this announcement reproduces  
fifteen of the 200 portraits which are to be seen in a  
portfolio at the exhibition at our offices.

\* \* \*

### The Lumière Colour Process.

A letter from M. Leon Vidal informs  
us that he has again visited Lyons, and  
that MM. Lumière were kind enough to  
show him a series of thirty or forty  
lantern slides by their new colour process, of which he  
speaks most enthusiastically as to the results. The latter  
included landscapes from nature, still life, interiors, sun-  
sets, and other scenes. In one Alpine view taken at  
Châmoûnix the summits of the mountains were covered  
with snow, which showed up against a brilliant blue sky  
flecked with white clouds, so that our correspondent says  
"it is impossible to conceive of its being rendered better."  
He promises a big future for the process, for, having been  
present at the development of a plate, he testifies to the  
simplicity and certainty of the operation. This plate had  
been made ten months, and was exposed on the day that  
M. Vidal saw it developed. The development is the same  
as with all other plates; the negative is then reversed,

developed in white light, and fixed. After washing and drying, the image is seen in all its colours. When examined in the hand there is no appearance of grain, and even when projected it is difficult to see the grain. Apparently the preparation of these plates has been so far advanced that it is now merely a matter of routine. This makes a tremendous step in advance, for all the colours are faithfully reproduced in one exposure on one plate.

\* \* \*

#### Picture Postcards.

In a recent paper by Mr. Frederic T. Corkett read before the Society of Arts some rather startling figures with regard to the picture postcard trade were given. It appears that in 1903 no less than 613 million cards were posted in Great Britain alone, while the total for Great Britain, Germany, Japan, and the United States was over three thousand million. The numbers have no doubt increased since 1903, and it is interesting to note that of the number now published in Great Britain two-thirds are of photographic origin, one firm alone issuing a million bromide cards a week, mainly of theatrical celebrities. It appears that the 2d. bromide cards and three-colour reproductions have the greatest popularity, though they are not the cheapest. The lecturer remarked that some of our manufacturers use a fourth printing in the case of the colour cards, which fourth printing, if carefully done, pulls the subject together and greatly benefits it. But he had found a great tendency to overdo this fourth printing, which requires very careful adjustment. British collotype cards appear to fail to reach the standard of the German productions by the same process, and Mr. Corbett is of opinion that the best work is none too good for the public who always appreciate quality better than cheapness.

\* \* \*

#### Mr. Joseph Pennell on Three-colour Work.

In the discussion on Mr. Corbett's paper Mr. Pennell made some remarks on three-colour work that will no doubt be received with mixed feelings by three-colour workers. He said: "The result of the reproduction of the old masters by the three-colour process was absolute rubbish; in fact, all artists agreed that three-colour work had always been rubbish and always would be." We have some recollection of certain artists expressing quite different opinions. Mr. David Murray, R.A., for example, quite recently said that he had "found great delight" in Cassell's publication, "The Nation's Pictures." He did not say the colours were perfect, but they served to recall the actual pictures to those who had seen them. "Some of the colour reproductions were extremely beautiful," he added, and this emphatic statement does not at all agree with Mr. Pennell's sweeping assertion that all artists are agreed that three-colour is always rubbish, nor with the rash prophecy that it always will be rubbish. Plenty of rubbish has been produced, but Mr. Pennell is very unfortunate if this is the only class of three-colour work that he has come across. There is also plenty of rubbish produced in the way of painting, but we do not judge the value of the craft of painting by the rubbish. As to the particular use of three-colour work in recording the work of either the old masters or the new, it is undeniable that this modern method of delineation in colour has already achieved notable successes, even though the process is not yet brought to perfection. As records many three-colour results are superior to laboriously produced copies made with the brush, for an expert copyist is seldom a good artist, while a good artist will seldom be a faithful copyist. We once met a man who had devoted his life to the copying of one picture, Leonardo di Vinci's "Last Supper." For many years, he told us, he had only pro-

duced copies of that picture, and therefore knew every detail of it; but when we compared his latest copy with the original there was so little real correspondence that we could barely regard it as a copy at all. It was of Leonardo as seen through the medium of the copyist, of Leonardo's touch, drawing, and colour were all absent from the copy, though it was the work of an expert of many years experience. Monochrome photographs of the two pictures are before us as we write, and the differences are marked. The photograph of the original is of much greater interest and value than that of the copy, and a good three-colour photograph of the original, if up to the standard of the best now obtainable, would, in our opinion, be of much greater artistic value than the copy itself, though it might cost fewer pence than the latter would pounds.

\* \* \*

#### Strenuous Press Photography.

The Titanic struggle between the Russians and Japanese in the war which is now almost forgotten—so soon is a great event blotted out by its successor—has had for one of its effects the issue of quite a small library of books illustrated and otherwise; but perhaps no volume gives so graphic a description of the whole course of the war from the departure of the Russian Embassy from Tokyo to the assemblage of the peace deputies at Washington, as a book of photographic reproductions published by "Collier's Weekly" under the editorship of Mr. James W. Hare, by whom a very large number of the photographs were taken. Mr. Hare, who is a son of Mr. George Hare, the veteran camera maker, was with the Japanese throughout the campaign for "Collier's," and (equipped with the war correspondents) carried his life in his hands over and over again in the use of the cameras with the firing line. The series of photographs which he has now brought together are more eloquent than words, putting before one the grimness and tragedy of war brightened by occasional examples of its humour. There is nothing to throw light on the heroic methods which must have been taken to secure many of the negatives save a word of acknowledgment that the "work was greatly facilitated by the use of the films and developing machines of the Eastman Kodak Company."

\* \* \*

#### The Tanning of Gelatine in Development.

A correspondent has called our attention to the fact that the paper by MM. Lumière and Seyewetz on page 285 of our issue for April 13 is confirmatory of one by Messrs. Haddon and Grundy which appeared in our issue for June 5, 1896, page 356, entitled "The Cause of the Relief in Gelatine Negatives," in which they tested the tanning properties of several of the developers. As a matter of fact, the title of the former paper might well have been used by Haddon and Grundy, for their paper is better thus described than by the title they used. With regard to the non-tanning action of glycin and paramidophenol, Haddon and Grundy infer that their oxidation products have no tanning action and are colourless, and that they do not oxidise when exposed to air even in conjunction with an alkali. In order to prove whether the oxidation products of these two developing agents did tan when oxidised, they used bromine as the oxidising agent and then on driving off excess and neutralising the free acid the dark brown solutions rendered gelatine insoluble even in boiling water, after only a few minutes' action. Whilst the well-known French chemists' researches include rather more developing agents, it is a matter of regret that they did not refer to the work of Messrs. Haddon and Grundy.

### "GOOD OR VALUABLE CONSIDERATION."

PRECEDENT as are the provisions of the law of copyright in literary and artistic works, a new source of doubt as to the precise position in which the photographer stands respecting his copyrights is created by the judgment in the recent case of *Stackemann v. Paton*, heard in the High Courts before Mr. Justice Farwell on April 4. Mr. Stackemann, the plaintiff, against whom judgment was given, took a very pessimistic view of the ruling of the learned judge in a letter which appeared in our issue of April 20. The case is one which certainly puts photographers on the *qui vive* as to the validity, in the eyes of the law, of practice which they have been accustomed to look upon as beyond question. Yet a consideration of the judgment will show that at the position taken by the learned judge is not as adverse as it looks at first sight. Nevertheless, it supplies the strongest warning that photographers must leave no precaution untaken in safeguarding their position regarding copyright in transactions in which copyrights created by them may be of value.

The case, according to the reported evidence, is as follows:—The plaintiff, Mr. Stackemann, trading as the Photographic Tourists' Association, was in the habit of taking photographs of boys' and girls' schools in various parts of the country. His method was to cause his aveller to pay a visit to the school, requesting permission to take series of photographs solely at the firm's risk and submit proofs. On permission being given, the photographer attended and obtained a series of interior and exterior views from the negatives of which proofs were submitted and copies supplied to the order of the proprietor of the school. The Photographic Tourists' Association also printed and supplied prospectuses containing reproductions of the photographs, and they relied on one source of their profits on the sale of such prospectuses. The two photographs which led to the action were each taken in this way. One was the exterior of a preparatory boys' school at Harrow, where a series of photographs were taken, including several interiors of rooms, a group of boys in running costume, and the boys' cricket eleven arranged in the field as if playing a match. In the case of the girls' school at Weston-super-Mare, the series included a photograph of some of the pupils in theatrical costume, and the interior of one of the bed rooms.

These two photographs subsequently appeared in advertisements of the respective schools published in *Paton's List of Schools, 1905*, the proprietors of the schools having sent to the publishers photographs taken by the plaintiff, from which they (the publishers), had made half-tone blocks which were printed in the list. At the time of the publication of the List the plaintiffs had not registered the copyright in the photographs, but they had afterwards done so, and the infringement which led them to bring the action was the subsequent sale of one copy of the List.

The point at issue in the case was whether the plaintiff had, or had not, received a good or valuable consideration for taking the photographs. If he had not, the copyright belonged to him; if he had, the copyright was the proprietors' of the school. This follows from the important proviso in Section 1 of the Act wherein the author of copyright is the owner also, *except*:—

"the negative of any photograph shall be made or executed for or on behalf of any other person for a good and valuable consideration, the person so executing the same shall not retain the copyright thereof unless it be expressly reserved to him by an agreement in writing, signed by the person for or

on whose behalf the same shall be so made or executed, but the copyright shall belong to the person for or on whose behalf the same shall have been made or executed."

From the evidence in the case, it is seen that no monetary consideration was made to the photographer for the taking of the photographs in the first instance, and therefore, according to all precedents in the courts, the copyrights in the photographs were the photographers'. The learned judge, however, laid an opposite construction on the evidence. In his opinion, the act of admitting the photographer to the school and permitting him to take photographs on the chance of selling them to the proprietors was a good consideration. He held that the fact of the photographs being made without any obligation to purchase did not affect this view of the case. Such a provision might be introduced into any contract, and he was not able to believe that it was the intention of the parties that the plaintiff should be allowed to sell copies of these photographs to the public. Mr. Justice Farwell thought that the case was not on all fours with that of *Ellis and Marshall (1895)*, where it was held that the sitting given by Miss Mary Moore to Mr. Ellis was *not* a valuable consideration, and where it was the intention of both parties that the photographer should have the copyright. In the present case it was held that the concession to Mr. Stackemann was a "good" consideration, and a judgment was given for the defendant.

This judgment, the learned judge pointed out, was not inconsistent with those in *Ellis v. Marshall* and in *Boucas v. Cooke*, though it is difficult, we must confess, for a layman to reconcile the last ruling with the two previous ones. Nobody will suppose that the concessions made to the plaintiff by the school proprietors were as valuable in a monetary sense as the permission granted by Miss Mary Moore to Mr. Ellis. Yet according to the judgment, the latter was not a good or valuable consideration, whilst the concession to Mr. Stackemann was at least, a "good" consideration. The learned judge, unless we are mistaken, is the first to draw this distinction between "good" and "valuable" consideration. And the only deduction to be drawn from his remarks are that the monetary value has nothing to do with determining the existence or otherwise of "consideration" to the photographer. In the *Ellis* case there is no valuable consideration, because the parties were agreed as to whose the copyright was to be. In *Stackemann v. Paton* there was "good" consideration because it was inconceivable that the photographer should have leave to sell copies of the photographs. We cannot help feeling that this is a very nice distinction indeed. The only consolation we can extract from it is that it clearly inculcates the necessity of there being, in such transactions, a precise understanding in writing, as to the proprietorship of the copyright. This might be done by getting the sitter, at the time of sitting, formally to assign the copyright to the photographer. This transference might be recorded on a simple printed form something to this effect:—

I, the undersigned, hereby assign the copyright in the photograph—or photographs—taken to-day of me by Mr. .... to him.

Signed.....

If practice be made of such assignment, the agreement, if stamped with a sixpenny stamp, could be produced in court as evidence. Such is the lesson of the recent case which unsettles, if it does not disturb, the position of photographers in regard to the copyright in photographs taken at invitation sittings.

There is one other lesson which the plaintiff in the case

we hope will pardon us for alluding to. It seems to us that the action was a tactical mistake. The damage which the plaintiff sustained by the publication of the two photographs in the defendant's list was a very slight one. We do not know to what other quarters the plaintiff looked for profit from his alleged copyrights in the photographs beyond the sale of prints and prospectuses to the schools, but we think it very unlikely that action would have been taken by the proprietors of the school against a paper which had reproduced a photograph supplied by the plaintiff. As a

point in tactics, and making the natural assumption that the plaintiff was satisfied as to his proprietorship of the copyrights, it would have been well to have overlooked the use by the school proprietors of the photographs in their own advertisements. The opposite, however, was done, with the result we have stated above. The case is certainly as "nice" as one as we can recall in copyright law, and we shall be anxious to notice the judgment should it come before the Court of Appeal.

## THE USE OF THE SPECTROSCOPE.

### II.

THE most convenient form of prism spectroscope is undoubtedly the direct vision instrument, for it is not only small, but can be fitted to any camera, or may be affixed to any light-tight box to which a dark slide can be fitted.

To use a phrase which is somewhat of an Hibernianism, the prism in these instruments is built up of three or five prisms, two of flint glass and three of crown, or one flint of very wide angle and two crowns. The explanation of the action of this train of prism is that one particular ray passes straight through, and this may be the green E or the yellow D ray, whilst the other rays are refracted to both sides of it, and the spectrum is therefore seen in a straight line with the slit.

I am not aware whether such prism trains are obtainable in England, though they probably are, but as a complete direct vision spectroscope can be obtained at prices varying from one to three pounds from Penrose and Co., it is hardly worth while fitting one up for oneself.

Between the prism and slit is, of course, a short focus collimating lens, which acts in precisely the same way as that described in the last paper—that is to say, it renders the rays parallel before falling on the prisms. For visual work there is generally a small eyepiece lens fitted, but for photographic work this is not necessary. Some of these spectroscopes have a supplementary tube carrying a very fine photographic scale, which is useful for visual work, as it can be shifted by means of a screw so as to make any number coincide with a given Fraunhofer line. This, however, I do not recommend; it adds to the cost, it is useless for photographic work, and with a little practice one soon recognises the principal lines at a glance, so that a scale is quite unnecessary.

Some also are fitted with what is known as a comparison prism, which is a total reflection prism that covers half the slit, so that one can obtain two spectra of different light sources at the same time. Whilst this is useful, it is not an essential, for one can obtain, as will be seen later, four or five spectra on one plate, and considering the present price of dry plates there is no necessity to be sparing of them. This prism, however, acts in the following way: When the spectroscope is directed to the sky and the comparison prism covers half the slit, our spectrum is just half the width it would be if the whole of the slit were used; but we can place a bunsen burner by the side of the spectroscope and in line with the comparison prism, and we shall obtain then, above or below the spectrum of daylight, the spectrum of any salts burnt in the bunsen; or if we use a vacuum tube we can obtain the bright lines of the gas in the tube. This enables the coincidence of lines to be very easily compared.

These spectroscopes can be obtained with a flange which can be fitted to any camera, but it will be found much more convenient either to build a wooden box specially; or one

of the old wood sliding-body wet-collodion cameras which can sometimes be picked up very cheap, will answer perfectly. In case, however, anyone wishes to make one, the following dimensions will serve: Extension of camera, 7 in., and the other dimensions 5 in. and 4 in. respectively, or such as will allow of any quarter-plate dark slide being fitted. The front must, of course, be made to shift either up and down or sideways, according to whether the longer side of the plate is horizontal or vertical.

There is one important point, and that is that either the front must possess considerable shift, or else the dark slide must be shifted, if more than one spectrum is required on the plate. It is immaterial which is adopted, but for those who are somewhat clumsy with carpenters' tools the former is preferable. The exact size of the front in such a case can only be calculated out after seeing the width of the spectrum and how far it is necessary to shift the spectroscope, so as to leave a narrow unexposed line between two adjacent spectra, but this it is easy to do by examination of a sheet of ground glass placed in the dark slide, and if the position of the front be marked for each movement it will be very easy to place it always in the same position.

There is one other point which is important. The axis of the spectroscope must not be placed centrally, as all our photographic lenses are, for the extension of the violet end of the spectrum is much greater than that of the red, and the consequence is that in most cases if it be placed central the red end will be cramped up close to the middle of the plate and the violet stretched beyond the other edge, and therefore lost. As a rule the spectroscope should be fixed about one inch above the centre of the front to one side or the other, or, of course, above or below it, according to the position of the longer side of the plate.

Mr. Ives made his camera with an angled back, so as to obtain a spectrum of the same width and sharpness throughout, and this is advisable, though not essential, for one soon comes to recognise a standard action in the violet, which is the end that must be swung out more than the red.

There is also one other accessory to this spectroscope, and one that I also advise for all forms, and that is a condenser in front of the slit. In Tallent's spectroscopic camera, which will be referred to later, this takes the form of an ordinary magnifying or reading glass mounted in an open framework, but the form I have used is a spherocylindrical spectacle lens of 5 in. focus mounted in an ordinary P.O.P. cardboard tube. With an ordinary lens the surfaces of which are segments of spheres the spot of light thrown on the slit is circular, whereas if a lens one surface of which is ground to a cylinder be used, and this surface be presented to the source of light, one obtains practically a line of light on the slit, and it is only necessary

make this line a little wider than the slit to obtain very satisfactory illumination. The idea of enclosing this condenser tube is merely to shut out side light, so that one can take the camera out into the open and point it to a white wall or blue sky, or work in a room in full daylight, and use a bunsen or incandescent gas flame, and not have stray light reaching the slit. This is a refinement, but as the condenser and tube costs complete not much more than a bellows it is worth using.

Practically these are the only two prismatic spectrographs that can be used for ordinary work. As I have already said, these spectrographs are intended for beginners and for general photographic work. For such work as the recording and measurement of wave lengths, the spectrum analysis of chemicals, or for the study of the infra-red or ultra-violet spectrum, then much more elaborate instruments are required, and those who want to undertake this work will know as well as or better than I do where to obtain the necessary data and instruments, and possibly also the money wherewith to buy them.

There is one very grave disadvantage in the use of prismatic spectrographs, if the user is ignorant of the particular point. In all spectra formed by a prism or prisms there is a cramping together of the red end of the spectrum and an undue extension of the violet, the result being that unless this particular distortion is known and allowed for totally misleading conclusions can be drawn from such spectrograms. There is also an undue absorption of the violet or ultra-violet end of the spectrum, which varies with the character of the glass. Some years ago when I obtained from Schott, of Jena, seven small prisms of a particular heavy flint glass, which gave great dispersion, intending, in conjunction with a friend, to make an automatic spectroscopic instrument. The prisms as we received them were of a diamond slit—that is, roughly cut to shape by a diamond wheel—but required accurately polishing to the required angle. We started, and after nearly six months' hard work, for we knew nothing about prism polishing, we had something that satisfied us. We set up our train of seven prisms, and then found that even with sunlight we could barely see the G line, so great was the absorption in the violet, and that spectroscopically we "got no forrarder." I occasionally look at the only one of the prisms that I have now left, and smile when I think of our wasted labour, to say nothing of my money.

With most direct vision spectroscopes the absorption of the

ultra-violet is pretty complete up to the end of the visible violet or the H line, and with some considerably weakened even beyond this; but provided one is content to accept the results given by increasing exposures on a plate, which is accepted as the standard, then there will be no difficulty in reading other results on other plates if the exposures be adjusted to their speeds, and the question of orthochromatising is in hand. If, on the other hand, the adaptation of yellow screens be undertaken, then this absorption of the ultra-violet may totally vitiate the results, for a yellow dye may be found which will give the required effect in the spectrum and yet fail in that it lets through that ultra-violet, which is absorbed by the spectroscope.

With the direct vision spectroscope no lens is required to throw the spectrum on the plate, though if one be used much sharper definition will be obtained, but as this lens introduces not only extra expense but also more glass and consequently greater absorption of the ultra-violet, it is better to omit it.

Having got so far, we may now consider one or two points which should be observed in practical work, and which apply both to the prismatic and diffraction grating spectroscopes. The first point as to the slit width. In Tallent's spectroscopic camera the slit is provided with a scale, and it can therefore always be opened to the same division, but for a slit which has no scale the best thing to do is to cut a very narrow strip off the side of a film negative, a cut film, not rollable; then open the slit, insert the strip of celluloid, and then close up the jaws till they just grip the celluloid, but so that it can be just pulled out. The slit is then just wide enough to obliterate all the lines except little *b* and *F*, which are seen very faint and diffused. Another method, which is visual and less certain, is to open the slit fairly wide, then close it down till the lines are distinctly seen, and then open up again till the lines just disappear. There is in this latter method more chance of error than the former, rough though this is.

Sometimes it will be found that one or more distinct black lines will appear running right through the spectrum, and not across. These are invariably caused by dust on the edges of the slit. The best way of cleaning the same is to take a small piece of soft wood, such as a match, pare the end down to a fine wedge, and insert between the jaws of the slit, and close the latter down till they grip the match fairly tightly, and then move the match up and down. This clears off the dirt.

E. J. WALL, F.R.P.S.

**DEATH of Mr. William Grove.**—It is with the very greatest regret that we record the sudden death on Monday last (April 30) of Mr. William Grove, the well-known photographer, of Baker Street. Mr. Grove had been suffering from a cold and had not been feeling well for some little time past, but there was no reason to suppose that his slight ailment was to take a suddenly fatal development into pneumonia. The deceased gentleman was of a quiet, reserved disposition, but willing on all occasions to give his service freely for the good of the profession of which he was an old and honourable member. He had been secretary and treasurer of the Professional Photographers' Association since its formation, and also served the Copyright Union in the capacity of treasurer. He will be missed from ranks where he rendered these public services, no less than from those where his personal qualities had made him a wide circle of friends. The funeral is fixed for Friday at Highgate Cemetery.

**THE "Barnet" Easter Competition.**—The following were the successful competitors:—First prize, G. H. Haycox, Worcester; 2nd prize, Easton Lee, Newcastle-on-Tyne; 3rd prize, W. J. Jones, Treatham Hill; 4th prize, G. A. Towers, Rugby. Honourable Mention: G. H. Haycox, A. M. Poole, S. W. Shore, John Lax, J. R. Richardson, J. Bannatyne, Rev. G. Larder, A. G. Thistleton, E. J. Jarvis, Thomas Summerson, R. Fraser, C. H. Jackson, C. E. Hether-

ington, Thomas Young, G. H. Kemp. Messrs. Elliott write that the general quality of the work was very much above the average, and gave a little more difficulty in placing the competitors than is usually the case. They will be announcing further competitions at an early date.

**MADAME LALLIE CHARLES**, society photographer, of Regent's Park, we gather from the papers, has experienced the enviable sensation of reading press notices of her decease. She took the course which, we believe, is now expected of all persons placed in this position. That is to say, she wrote stating that the report was "grossly exaggerated." Mark Twain scarcely guessed, perhaps, how soon his phrase would become universal.

**DESCENDING** a steep bank at Chester-le-Street one day last week, a Bensham photographer named John Sidaway collided so violently with a trolley or roller that he was rendered unconscious, and one of his legs badly injured.

"A New Terror to Aliens" is the phrase which the "Daily Chronicle" kindly refers to the new regulation made by the Secretary for Scotland that any alien awaiting deportation, who is confined in any prison until the Secretary of State has decided upon his case, may be photographed and measured in the same way as a convicted criminal prisoner.

## NATURAL BACKGROUNDS IN STUDIO PORTRAITS.

THE combination of a suitable background representing some natural scene in the portrait taken in the studio is more in demand from the photographer than may be thought by those who hear only the outcry against backgrounds of all kinds, except the severely plain. True, many good photographers have discarded all backgrounds but those of plain cloth, and with good results. Yet that is not to say that a background full of detail should not be fitting to a portrait. One series of portraits which occurs to us as we write is that of British mountaineers taken by Messrs. Elliott and Fry, in which

paintings. The transparency is held in a frame within the camera by means of which it can be pressed film to film into contact with the plate in the dark slide when the shutter of the latter is withdrawn. The attachments to this carrier frame permit of it being turned down on to the bottoms of the camera, as shown in Figure 3, the adjustment being made by the lever outside the camera. This movement, from horizontal to a vertical position in contact with the plate, is made with certainty in an instant. With the exception of a black and a white background, there is no other special apparatus required.

Fig. 1.—Arrangement of the Lighting for the First Exposure of the Sitter

Fig. 2.—Position of the Transparency When Making the First Exposure Under the Lighting Shown in Fig. 1.

Fig. 3.—Arrangement of the Lighting for the Second Exposure of the Sitter.

Fig. 4.—During the Exposure Under Lighting as in Fig. 3 the Background Transparency is thrown forward as shown here.

the subject is chosen against an appropriate background of mountain or pass. We are not sure, but we believe in these photographs the man was photographed against a plain ground, the scene afterwards drawn to suit, and the two combined in a new negative. Such a method, and others which are known and practised, are cumbersome and expensive in comparison with a new system which we here describe and illustrate. It is the invention of a Swiss photographer, Herr Dischner, and has been brought to our notice by Dr. J. H. Smith, of Zürich, the holder of parti-proprietary right in the English and other patents. In the Dischner method the background, which is to appear in the photographs, exists only as a positive transparency on glass, the negatives for such transparencies being made from natural scenes, or, if thought desirable, from drawings or

The *modus operandi* will be understood from the figures. The sitter is posed in the ordinary way, his position on the focussing screen being viewed with the transparency in position, upside down as shown, in order that he may be disposed in harmony with the background. He is then illuminated from behind through a white screen, and a very brief exposure given with the background in contact with the plate. The result is an impression of the background, except where the image of the sitter falls; here the plate remains unexposed. A dead black ground is then let down, the studio (artificial) light switched on to illuminate the sitter in the usual way, and a second exposure made without the sitter having moved from the position first assumed, and with the background transparency thrown back. The total time of the two exposures, is

pointed out, need not be more than three seconds, when the operator and his assistant are accustomed to working the process. The results by the new method, which by courtesy of Dr. Smith we saw in this issue, speak more than columns of words for the success of the process, and for the highly effective use which can be made of it. The life and movement of a big city or river introduced as a background to portraits which need suffer from none of the tech-

method will permit of scenes being photographed in the studio against the scenery actually used on the stage. The separation of the operations of photographing the actors and the *mise-en-scène* will benefit both. The final result of combining the two through the medium of the scenery-transparency should be more realistic than a group without scenery taken in the studio, and technically much superior to the actual scene photographed on the stage.

Figs. 5 and 6. Reproductions of Photographs made of Sitters in the Studio with Introduction of the Natural Background by the Dischner Method.

cal defects of those taken out of doors, introduce a new note into photographic portraiture, and provide facilities by which photographers of all classes should be able to benefit. It is surely superfluous for us to point out how the photographer, say in a seaside resort, will be able to represent his sitters on the sands, or in the vicinity of the "show place" of the district miles, perhaps, from the town. It is conceivable also that in theatrical photography the

We may add that the method above described is patented in all countries, and therefore is not available for use by a photographer, privately even, under penalty for infringement. The apparatus, and appurtenances, however, are to appear on the market before long, and those who feel interested in the process may address enquiries to the representative of Dr. Smith's interests in this country, Mr. Oliver Dawson, 254A, High Holborn, London, W.C.

## AMERICAN PHOTOGRAPHERS IN CONFERENCE.

### THE CONVENTION OF THE PROFESSIONAL PHOTOGRAPHERS' SOCIETY OF NEW YORK.

FOLLOWING on the presidential address of Mr. Dudley Hoyt, before the Convention in New York of the P.P.S. of N.Y., we are able to give this week from the "Photographer," the official organ of the Society, a report of the discussion of some of the questions in the light of which the Society had issued to its members some weeks before the Convention. It will be seen that the discussions, as is most inevitable in such cases, leave the question pretty much where it was, but the views of the Americans will nevertheless be found of serving of perusal by English photographers. The problems to be solved are common to both countries, and it may be beneficial for

certain of them to be discussed in our own columns in their special relation to conditions in this country.

An error of a single letter in our notes of last week led to an apparently grave charge against our good friend, Mr. Pirie Macdonald, of which we hope we were judged innocent by anyone who noticed it. The employment of "his" instead of "its," made us suggest that Mr. Macdonald was using the Professional Photographers Society for his private ends. The exact opposite is the case; Mr. Macdonald has devoted a large share of his time and earnings to the ends of the Society.

#### FREE SITTINGS.

Under what circumstances is the photographer warranted in offering a free sitting?

Mr. Gessford: I believe the photographer is warranted in offering a free sitting under all circumstances. It does not necessarily imply because you give a free sitting that you are willing to give away a

dozen or two photographs. Very often a free sitting results in a deal amounting to 30 dols. or 40 dols. That is my own experience.

A Member: I may give my experience in that direction. I have

NATURAL BACKGROUNDS IN STUDIO PORTRAITS.

A Specimen of the result of the Dischner Process described on another page.

made for the last five or six years photographs of aged people over sixty, free of charge, and present them with one photograph. I had been many times troubled with requests to photograph people who were dead, and an idea struck me that if I photographed them when they were old, and kept the plates, I might have something to do after they were dead. By following this plan I have obtained and have a very valuable lot of negatives of old folks over sixty. Very often they drop off, and in the course of time I have very good orders for them.

Mr. Bradley: I should think this would prove an interesting subject. Can't we hear more of it?

Mr. Farrington: My experience has been somewhat like that of the last gentleman speaking, although I have made the age seventy instead of sixty. Over seventy anyone who desires can come to my studio and have a sitting and have one photograph free; and I have received many orders.

Mrs. Beals: Do they require a birth certificate? (Laughter).

A Member: I find it sometimes pays to offer free sittings—not necessarily to give away pictures. For a new man starting in a new place it pays pretty well.

Mr. Waide: It is my experience that it is oftentimes wise to give what might be called free sittings, but I do not consider the kind that I have made as free sittings. It is human nature for people to think more of things they get for nothing than of something they pay for, and at times when you can give them something of that sort they will deliberately go out and work for you, and, as Mr. Ray just stated, for a man just starting out it is very wise to give people something that they think they are getting for nothing, and they are willing to go out and work for you.

Mr. Pomeroy: These photographers have begun by photographing

the aged. In Kansas City I commence at the other end. I issue a circular and send it to each mother after a child has been born. The birth notices are printed in our paper each day, giving the address, and I send the circular, congratulate them on the birth of the new-born babe—"May it live long," and so forth—and, if they wish, I will make its first photograph free. I consider this one of the best ads. I have.

Mr. Parkinson: I don't think it is in good taste to send agents to hotel arrivals and make a practice of inviting everybody that comes to your city to come to your studio and have a free sitting, although I do not question any man's right to do that. It is a business, and friendship is friendship, and we have a right to do whatever we please in that regard. I give a sort of a free sitting quite often, and then I make the pictures and show them to the man, and he often gives me an order, for which I only charge him 20 cents. Sometimes I am very good to them—I give them pictures for 15 cents, because I took it without any intention of their buying it, and I have often thought I ought to do that oftener than I do.

What I arose to say specially was something that Brother Waide made me think of. My experience has been that the people I charge the biggest price to, if they are fairly satisfied, do the greatest amount of work for me. The deadheads take the pictures and they do nothing, as a rule.

Mr. Core: Before we get too enthusiastic on this free sitting game, it might be well to say something on the opposite side. We are in a dilemma right now, and that is with regard to copyright. There have been so many photographers ambitious to have photographs published that we are only too glad to furnish them on the slightest provocation to the newspapers, etc., and now that thing has reached such a stage that we are trying to guard against the very thing that

created. The satisfaction of seeing your picture and name in a magazine was considered ample compensation for your trouble. This

scheme is all right, but it wants to be tempered with a good deal of judgment, in my opinion.

### SPECULATING LARGE PLATES.

"In the Long Run, Does It Pay to 'Speculate' Larger Plates or Pictures?"

Mr. Hollinger: My business is altogether speculation. I don't care whether you think it pays or not—outside of duplicates our business is altogether speculation. I don't care what people want I just make what I think I can sell. I make all sizes, and I make everything on speculation. They never pay a deposit, and I don't

care what they want, and we just depend on tempting them to buy what we make. I make all sizes, without caring anything about it. I just measure up the customer and do that, and we do that every day. That is what I call selling pictures on their merits and tempting people to buy. I tell you here to-day whatever you decide I will never do anything else but the way I am doing.

### SCHOOL RATES.

"How can a Uniform and Equitable Rate be Fixed on School and Class Work?"

A Member: I would like to ask if that means uniform for every photographer in the United States, the State of New York, or the City of New York, or just in one particular school or college, or what meant there. Mr. Hoyt, will you explain?

The President: Well, I will tell you what we have done in Rochester. We came together on a question of that kind. There was a lot of school work and no returns; it did not mean anything only a lot of work, but at the same time we felt that if we could get that work somebody else would not. The result was that we supplied a demand for no profit, and with that in mind we came together on one fixed price, that each photographer was to state a price that he was willing to make for a certain number of sittings; and after stating the price, which would be such as he felt would be the lowest possible price that he would care to give under any conditions, and

in giving that price the others did the same thing, and in that way they formulated a minimum rate, and there was to be a discount for the number of pictures asked for or number of sittings. Now, if there were more sittings than contracted for—for instance, a class came in and said we want a price on a hundred sittings, there would be one hundred in that class, and the result was to bind them and know what we were dealing with and make it a business transaction. The committee from that class should bring a list, and with that list one dollar for each person that was going to sit, and wherever they decided to go they deposited that dollar in their name. The result was it was a business transaction to commence with, you were sure of so much business to commence with. Then you would give them your discount for that number; but where there was no list the regular prices prevailed. That is the condition of school work in Rochester to-day.

## THREE - COLOUR AT THE CROYDON CAMERA CLUB.

The syllabus of the Croydon Camera Club announced a conversational meeting, and Mr. S. H. Wratten and Mr. Mees found the topic, the former having kindly made arrangements for testing the members' light-filters and safe-lights, and the latter giving an impromptu and interesting address on various points connected with three-colour work and orthochromatics.

### Three-colour Filters.

Starting with diagrammatic representations of the spectrum, the varying sensitiveness of different plates were shown, from the "ordinary"—on which the ultra-violet and invisible end had as much action as the entire visible spectrum—to the modern bathed plate, sensitive well into the red. In three-colour work, Mr. Mees pressed a decided opinion, that the best practice was to divide the spectrum sharply into three parts, with but small overlap. No set of commercial filters he had seen were correct, the red letting through considerable amount of green. How undesirable this was might be seen by a simple example. Suppose a red geranium and its foliage were to be reproduced in colours, then, in the case given, both the red flower and its green leaves would record through the red filter, grading the green to a more or less brown hue. With a really sensitive plate, a very deep screen was not only unnecessary, but detrimental. The weak point in three-colour work—viz., exposure, is directly dependent upon the efficiency of plates and filters. Up to the present, assuming the very best conditions, and a one-exposure camera, two seconds might be roughly taken to represent the minimum time requisite for a portrait in the studio. Out of doors he had obtained a satisfactory record through a correctly adjusted shutter in 1-25 second, on a pinacyanol-bathed plate.

### Spectrum Test of Filters.

Various sets of three-colour screens were then tested by means of the spectrum projected on the screen, including the "Rotary," "Pinatype," "Staleys" (Dr. Miethe's), and others. The cheapness of the last-named should certainly appeal to those who wish to make a trial trip in three-colour work. It was hardly possible to judge of the respective merits of the filters thus shown, one set having, say,

a better red filter than another, whilst being somewhat inferior in regard to green, or blue, as the case might be. "Black" in a filter, Mr. Mees said, was to be avoided, as it damped the spectrum generally; it was, however, purposely introduced into the blue filter to bring the exposure within manageable limits. The spectrographs, of Wratten's bathed pinacyanol and pinachrome plates, and the new Verichrome, were next shown. All showed distinct traces of gaps, though the majority of these, Mr. Mees stated, only appeared when artificial light was used, not when daylight was the illuminant. The pinacyanol plate had a characteristic gap in the green, but is nevertheless the best for three-colour work, owing to its high red sensitiveness. The pinachrome plate showed the usual excessive sensitiveness to blue, and then ran with a fairly level band into the orange. For landscape (monochromatic) work, a simple yellow screen would only be necessary to damp, or keep back, the blue. The Verichrome appeared to have much the same attributes as the last-named, but was not so fast in the yellow or orange.

### The Screen for General Work.

The best screen to employ for subjects not having much red was a dyed film of tartrazine, of such a depth as to require an approximate increase of exposure  $\times 10$  for the usual commercial ortho plate. With the new Verichrome, the same screen would drop to 4, and with the pinacyanol and pinachrome-bathed plates to 3. It was quite easy, the lecturer said, to give an apparently increased colour sensitiveness by dyeing the film of the plate, at the same time slowing its speed. A filter would, however, answer every purpose, with the advantage that it might be removed when very short exposures became obligatory. A number of commercial and home-made ortho screens, or light-filters, were next tested. The pot-metal, with one exception, all contained a large proportion of black, as did, somewhat curiously, a stained auramine one. The tartrazine and naphthol yellow screens were undoubtedly the most efficient. The last, Mr. Mees said, cut the blue too abruptly. Picric acid screens darkened on exposure to daylight.

In the discussion which followed, Mr. C. E. M. Bennett said he should object to developing the pinachrome plates in total darkness,

as advised. Could no light be used? Mr. E. A. Salt inquired whether "colour" could be correlated to wave length? The question of monochromatic rendering was in many cases difficult, notwithstanding arguments to the contrary. He very much doubted whether a red and blue of equal luminosity, and in juxtaposition, could be said to be satisfactorily rendered in monochrome by a plain level tint. He noted that in three-colour work Mr. Mees thought it best to divide the spectrum somewhat sharply. Why was not a fair amount of overlap permissible? Mr. Mees, in reply, said with the bathed pinachrome plates a very little light might be used, just sufficient to see dishes, etc. A blue-green light would be as good as any; a red light should not be used. The pinacyanol plates must be developed in total darkness. In answer to Mr. Salt, he said that colour, *per se*, would not be identified with wave length. In the case of monochrome reproduction of equal luminosities of red

and blue, he should differentiate by making the red the lighter of the two. An engraver would render both alike. He agreed that colour rendering in monochrome was difficult if tonal values were to be preserved. Its interpretation required a skilled photographer and artist in one. It was preferable for the three-colour screens to cut fairly abruptly; a better colour rendering was obtained than in the case where much overlap was allowed.

At the instance of Mr. H. P. C. Harpur a most cordial vote of thanks was accorded Mr. Mees and Mr. Wratten. The latter, in responding for both, said the time would come—indeed, it had already come—when one might use orthochromatic plates for every class of work (except copying black and white), with undoubted finer all-round results. It was, however, necessary to learn how to get the best out of them, just as photographers had to master the idiosyncracies of the ordinary dry plate when first introduced.

## ANALYSIS OF THE MOTION OF THE SIMPLE PENDULUM.

[THE following article, written in reference to the recent discussion on the pendulum method of determining shutter speeds, will, it is believed, be found valuable as pointing out the conditions under which the pendulum can be used with accuracy.—Eds., B.J.P.]

The writer has frequently noticed what erroneous ideas are commonly held as to the motion of a simple pendulum, and the columns of the B.J. have recently given examples of these misconceptions. With a view of giving a lucid account of this motion, an analysis of the movements of a simple pendulum, 2 ft. long, and swinging in an arc 30 degs. each side of the centre line, is given.

It is usually stated that for all practical purposes the "period" of a simple pendulum is constant whatever be the amplitude of the swing. This statement is only partially true for an amplitude of a few degrees, and when a larger swing is given is wholly inaccurate.

The "period" of the pendulum (by which term is understood the time that elapses from any position of the pendulum to the time that it has returned to the same position travelling in the same direction)

is approximately stated thus.  $T(\text{secs.}) = 2\pi\sqrt{\frac{l}{g}}$

Where  $T$  = the period in seconds.

$\pi = 3.1416$ ,

$l$  = length of pendulum in feet.

$g$  = force of gravity at the place of experiment 32.2 is sufficiently approximate.

It must be mentioned here that  $l$ , strictly speaking, is the length of the equivalent simple pendulum, but if the plumbob be a small, round, and heavy object, and the suspending cord be very fine,  $l$  may be reckoned from the point of suspension to the centre of gravity of the plumbob.

Now, this approximation is only good enough for such short swings that would be quite useless for shutter testing.

A much closer approximation to  $T$  is

$$T = 2\pi\sqrt{\frac{l}{g} \left\{ 1 + \frac{1}{4} \sin^2 \frac{B}{2} \right\}}$$

where  $B$  is the angle of swing measured from the centre line of suspension.

This formula is good enough for 30 degs. of swing each side of centre line, but for greater swings the formula is more complicated, as further terms must be introduced, and for a rigid computation elliptic functions must be brought into use.

To find the linear velocity of the bob of the pendulum at any moment of its swing, it will perhaps be best to state the case as follows (a statement which is not made strictly scientifically, but which avoids the use of the integral calculus).

One may say that the linear velocity of the centre of gravity of the bob of a pendulum is the same as that attained by a weight dropping from rest (in vacuo) through the same distance that the pendulum bob has moved vertically. This may be recognised by imagining the falling weight to be constrained to move in the arc of a circle by a cord, and hence converted into a pendulum.

Now a falling weight is acted on by a constant force gravity ( $g$ ) and hence has a constant acceleration,  $g$  feet per sec. per sec. Consequently, starting from rest, at the end of  $t$  secs., will have attained a velocity  $V$  feet per sec.  $=gt$  ( $a$ ) and will have fallen say " $h$ " feet. Now as the acceleration is constant the average velocity will have been  $\frac{1}{2}V$ .

Hence average velocity  $\frac{1}{2}V \times t = h$ .

$$\text{or } t = \frac{2h}{V} (\beta)$$

Substituting this value of  $t$  in ( $a$ ) we get

$$V = \frac{2hg}{V} \text{ or } V = \sqrt{2hg}$$

$h$  may be found as follows

$$h = mn.$$

$$mn = On - Om.$$

$$= l \cos \theta - l \cos \beta.$$

$$= l (\cos \theta - \cos \beta).$$

$$\cos \theta = 1 - 2 \sin^2 \frac{1}{2} \theta.$$

$$\& \cos \beta = 1 - 2 \sin^2 \frac{1}{2} \beta.$$

$$\therefore mn = h = l \left( 2 \sin^2 \frac{\beta}{2} - 2 \sin^2 \frac{\theta}{2} \right)$$

Substituting this value of  $h$  in the formula for  $V$  we find

$$V = \sqrt{2 \times 2gl \left( \sin^2 \frac{\beta}{2} - \sin^2 \frac{\theta}{2} \right)}$$

$$V \text{ feet per sec.} = 2\sqrt{gl \left( \sin^2 \frac{\beta}{2} - \sin^2 \frac{\theta}{2} \right)}$$

If we wish to convert the velocity into radians per second we must divide by  $l$  giving velocity in radians per sec.

$$= 2\sqrt{\frac{g}{l}} \left( \sin^2 \frac{\beta}{2} \sin^2 \frac{\theta}{2} \right)$$

If degrees per second are desired this must be multiplied by 57.3. From this a table has been calculated for the given conditions showing the time taken by the pendulum to travel over each 5 deg. of arc. It will be noticed that the last 5 deg. takes between three and four times as long as the first.

③ Time of executing 5° of arc.

0°	0.0423 seconds.
5°	0.0436 seconds.
10°	0.0465 seconds.
15°	0.0524 seconds.
20°	0.0658 seconds.
25°	0.1474 seconds.
30°	

$\frac{1}{2}T = 0.3980$  seconds.

The period of the pendulum swinging in these conditions is 1.593

calculating from the usual formula  $T = 2\pi \sqrt{\frac{l}{g}}$  the period would

be given as 1.565 secs. or an error of 2%

For the guidance of any photographer who may wish to test his meter by this method, it may be mentioned that to avoid giving initial impetus to the bob it should be held in its position of rest and swing by a piece of cotton and released by touching the cotton with a match.

The writer is sure that with ordinary care and adherence to the methods and dimensions given, a most accurate determination of meter speed can be made.

Propos of the method of testing speed by revolving a bicycle wheel it may be as well to state two precautions to be observed to render the result fairly accurate.

The valve should be wholly removed, so that the wheel is in motion in all positions.

A number of revolutions should be timed, say twenty, and the exposure made at the tenth thus eliminating any effect of friction and wind resistance.

HARVEY COLLINGRIDGE, B.Sc., A.M.I.C.E.

## Exhibitions.

### THE NORTHERN PHOTOGRAPHIC EXHIBITION. MANCHESTER.

THE Northern Photographic Exhibition (Manchester) was formally opened by the Right Hon. the Lord Mayor of Manchester on Friday, the 27th, at 7.30. Many weeks of patient labour by many sub-committees were—under the guidance of the executive—brought to an issue which must be pronounced highly successful. We understand that the judges marvelled at the amount and quality of the work submitted to them, for upon the walls are to be found not only the cream of the best exhibitions held in this country, but also much new and striking work, both British and foreign.

The Northern Exhibition is not sectarian. It is not a "Royal" show only. Neither is it a "salon" show only. It is both. It is catholic, and we understand that it is the determination of those in authority to maintain this catholicity as a distinctive feature.

When an exhibition is worked by sub-committees certain risks are run, risks of omission and risks of overlapping. At Manchester, however, the work of each sub-committee was so clearly defined at the outset that all have worked together with the perfection of the wheels of a clock. The sub-committees were as follows:—Hanging; Catalogue; Lantern; Advertising and Press; Plaque; Lectures; Reception; and Finance. This latter consisted of the chairman and general secretaries of the exhibition, together with the secretary of each sub-committee, so that the entire expending powers of all departments were focussed and controlled. When work is thus divided, and when each committee has only as much to do as it can do well, it is not a matter of surprise that so fine a show has been got together without undue "booming."

The pictures are very pleasingly arranged. They are 478 in number, and are, perhaps, rather crowded. The lantern slides are admirably shown, being arranged in the form of a square, with powerful electric lights inside the square. They can thus be viewed with perfect ease, notwithstanding the general lighting of the room. The bulk of the work sent in is, as might have been expected, British, but there are also contributions from Italy, Germany, Austria-Hungary, India, and Spain.

The catalogue, like all "Northern" catalogues, is very handsome, and contains twenty-four illustrations of excellent quality. In this matter the executive have been indeed generous, almost prodigal. It is well worth the sixpence charged for it.

As the catalogue does not take account of photographic processes it is difficult to say how favours are distributed, but we imagine that the new toning formulae for bromide papers have given that process a new lease of life.

We do not here pretend to give anything like an adequate review of the pictures as a whole—there are too many good things to admit of that in the space at our disposal. We must be content to notice only a few which are either really prominent, or have been made so by having honour thrust upon them. It is remarkable that the award list in the pictorial section contains the names of no travel-stained, plaque-laden picture, and this may be taken as an indication of the freshness of the whole exhibition. R. Dührkoop has many fine exhibits. He has better work here than "Hermelin," which receives a plaque, but he has nothing more clever than "Twilight," which receives a like honour. Not that the latter was beyond improvement. There is a high light on the collar of the male figure and another upon the wall, both of which are obtrusive. We shall certainly hear a great deal of Dührkoop if he continues to support British exhibitions. Miss W. H. Aitchison has found the "soft" side of the judges with her "Ghetto." It is a delicate piece of work of the chalk-drawing type, representing an arched street, with the distance in sunlight. It is a likeable thing, but not specially impressive. "A Lonely Road," by Basil Schön, is a delightful bit of pure unadulterated photographic work. It is both forceful and impressive, and the "loneliness" of it needs no title to indicate its motif. The snow and the light falling upon it from an opening in the trees are admirably rendered, and the whole is presented with conspicuous good taste as to mounting. J. C. Batkin takes the fifth place—for the judges have placed the successful pictures in the order of their merit in

the award list—with "A Rift in the Fog." This is great. It is one of the finest things we have ever seen, or, rather, we should say, it could easily be made such by a very slight modification. The picture presents the old contest between light and fog. Both combatants are in dead earnest. So far as the battle has already gone we cannot say which will win, but our hopes are set on the light. Cabs and buses move along in the shrouded day, and it is just in the nearer cab and figures that we would prefer modification. These seem to jump a little out of their proper planes and to come too near us.

"Ileene," by R. R. Hirst, is not an unpleasant face, though it is tearful and sad. It is not a specially striking picture in an exhibition where so many things are so good. But, after all, art is a very personal thing, and we are not so unreasonable as to demand that judges shall look at all pictures through our spectacles. The popular judgment—of which we think little in these matters—will regard "Ileene" as lucky.

"A Muslin Gown," by Mrs. Barton, has been treated with rare grace in being awarded the seventh and last plaque in the pictorial print section. Frankly, we do not understand this award. A lady stands clad in a muslin dress. She seems ill, or, at least, ill at ease. She seems, further, to be endeavouring to support her weight with both hands, which rest—one on something on the right of her, and one on something on the left of her. The something on the right may be a dressing-table, the something on the left is not distinguishable. The *locale* may be a bedroom, but if so it is rendered as the interior of a cave. A dense—almost detail-less—blackness surrounds the figure. In the matter of subdued shadow detail the difference between Mrs. Barton's print and Dührkoop's "Twilight" is exactly as the distance from the North Pole to the South. The two are together in the exhibition. Some malicious "hangman" must have done this.

We should like to have referred to many more, but that is not possible in this notice. We must, however, congratulate Mr. Marshall on his "Seaborne." It is not every man who can see the pictorial possibilities of a cargo of coal lying upon a quay. On the face of it that is all it is, but the treatment has made it much more. In Mr. J. M. Whitehead's "The Night Cometh" there is more than sentiment, there is also exquisite technique. He does not seem to have attempted to make the unwilling sun to shine just out of that patch of sky and just on to this patch of earth as Mr. A. Horsley Hinton seems to have done in his picture "In Airedale," producing a distinctly artificial and stagey effect. The sun has a way of his own, and when we interfere with him it is often to our own hurt.

The pictures were judged and the awards made by Archibald Cochrane, Ernest Marriage, F.R.P.S., and Frank M. Sutcliffe. We append the official list:—

Pictorial Section Prints.—Plaque 1, "The Hermelin," R. Dührkoop; plaque 2, "Twilight," R. Dührkoop; plaque 3, "The Ghetto," Miss W. H. Aitchison; plaque 4, "A Lonely Road," Basil Schön; plaque 5, "A Rift in the Fog," J. C. Batkin; plaque 6, "Ileene," H. R. Hirst; plaque 7, "A Muslin Gown," Mrs. Barton. Hon. mention.—1, "Building the Bridge," E. T. Holding; 2, "Breakfast," Dr. E. G. Boon; 3, "A Sunlit Clerestory," S. G. Kimber; 4, "Reading," F. H. Crossley; 5, "North Aisle, Winchester," W. A. Clark; 6, "A Study in Monochrome," Dr. A. T. Lakin; 7, "Japanese Anemones," Dan Dunlop.

Pictorial Section Lantern Slides.—Plaque 1, "Fête on the Assumption," Dr. G. H. Rodman; plaque 2, "Mother's Help," Rev. H. W. Dick; plaque 3, "Sunlight in Old York Church," W. A. Clark. Hon. mention.—1, "Tree in a Mist," Ellis Kelsey; 2, "Storm Lifting," C. F. Inston; 3, "Figure Study," W. A. Taylor.

Technical and Scientific Section for Prints.—Plaque, "Pollen of Hollyhock," Dr. Rodman. Hon. mention.—"Home of Spider," H. C. Simpson.

For Lantern Slides.—Plaque, "Smelt," Dr. Francis Ward. Hon. mention.—"Pollen of Hollyhock," Dr. G. H. Rodman; "Salt-making," T. E. Leigh.

The following is the full list of lantern lectures:—April 27—opening ceremony and conversazione; April 28—S. G. Kimber, Esq., "Winchester Cathedral"; April 30—Fred W. Saxby, Esq., "Marvels of Insect Life"; May 1—Dr. Wm. Murray Cairns, "Japan and the Japanese"; May 2—Dr. John W. Ellis, "The

Pilgrim's Way"; May 3—J. J. Phelps, Esq., "Old Manchester and Salford"; May 4—Godfrey Bingley, Esq., "London to North Cornwall"; May 5—W. A. Clark, Esq., "Mediæval Architecture"; May 7—exhibition of competition slides.

## THE BIRMINGHAM PHOTOGRAPHIC SOCIETY AT RUSSLEY SQUARE.

THE opening of the exhibition of photographs by present members of the Birmingham Photographic Society took place on Monday evening last, when a short paper, prepared by Mr. Harold Baker, was read by Mr. P. Bale Rider, who expressed the regrets of the Birmingham photographers that they were not able to be present. Mr. Baker's paper consisted in a short review of photography as it has been practiced in Birmingham, a recital notably undertaken for the glory of the Midland capital. However, it should be said that Mr. Baker's eulogies were confined to the past practitioners of the art in Birmingham, and the blushes even of Mr. Page Croft would have been spared had he been present. The paper noticed the work done in the early days of photography by Dr. Hill Norris, Alfred Humphrey, O. Rejlander, H. P. Robinson, W. Willis, Alexander Parkes, and George Marlow, all of whom at one time or another were members of the Birmingham society which preceded the present one. Mr. Baker might also have mentioned the name of Laroche, who was colleague of the famous photographer, Napoleon Sarony, in Birmingham. Laroche was the defendant in the celebrated law suit in which Talbot claimed patent rights in the wet collodion process.

The reading of the paper was followed by a short discussion chiefly appreciative of the work on the walls, among the speakers being Sir Joseph Swan, Mr. J. C. S. Mummery, Dr. Grindrod, and Mr. J. C. Warburg.

The photographs on the walls include many pictures which are familiar to visitors to the London exhibitors of recent years. We understand the exhibits were selected by a committee which too upon itself in some cases to suggest to members what pictures they should show. Thus Mr. Smedley Aston is represented not only by his recent portraits in which the influence of the Pre-Raphaelite painters can be seen, but also by an early photograph of his—one of the notable productions of pictorial photography, we think—"Reminiscence" (No. 37).

We are particularly glad to make the acquaintance again of Mr. W. T. Greatbatch's beautiful work, examples of which are shown in the "Orchard" (No. 661), and "Autumn Haze" (No. 62). Mr. Cruwys Richards shows to better advantage in the present collection than he did at the recent Birmingham exhibition, for his later work in gum-bichromate has not the charm about it, in our judgment, which his earlier figure studies possess. Other workers whom it is a pleasure to meet again are Bernard Moore, C. S. Bainton, William A. Clark, George Arbuthnot, J. C. Batkin, and Miss Marian Silverston. Mr. Harold Baker contributes a few large and striking examples of his portraiture, and Mrs. Barton is represented by one or two specimens of her characteristic work. Dr. Grindrod and Mr. Harold Holcroft both members of the Birmingham Society, add to the collection of photographs, the total number of which is seventy-eight. It is a collection which represents pictorial photography of a very high order, and we can commend a visit to 66, Russell Square, to all those who study the work of some of our leading exhibitors.

## COBURN'S PICTURES IN LIVERPOOL.

AN exhibition of the works of Alvin Langdon Coburn at the rooms of the Liverpool Amateur Photographic Society was opened informally on the afternoon of Monday last, April 30. There was no opening ceremony and no speeches, but a large number of amateur photographers and their friends, several well-known Liverpool artists, a number of gentlemen interested in the promotion of art in the city, and many well-known citizens attended to give the show a good send-off.

The idea of holding this, the first provincial exhibition of Coburn's works, came from the hon. sec., Mr. C. F. Inston, who thought that the educational value of this one-man collection would be of the greatest help in stimulating many members of the society towards pictorial, as opposed to technical, photography, the pictorial work in Liverpool being unhappily rather neglected.

As soon as the idea was mooted it was eagerly taken up, and thanks to the generosity of J. Dudley Johnston, Esq.—one of the editorial workers—and the help of a few others, arrangements were on concluded with Mr. Coburn.

So much has already been written on the pictures that detailed criticism is not required. The portraits form a most striking group, whilst the well-known scenes from London, Edinburgh, Rome, and Venice, are all of great interest. Of the landscapes four snow pictures are very realistic, the rendering of the tones of the first snow being uncommonly good.

The greatest interest is naturally centred on the group of seven studies—taken especially for this exhibition—of the Liverpool Docks. What can we say of these? Here have we been living in and around these docks for years, seen them photographed from what appeared to be every point of view, and yet Mr. Coburn comes down for a short half-day and obtains "Coburnesques" such as we have never even dreamed of. All the seven are interesting; three stand out pre-eminent. Of these three one entitled "Spider Webs," the motive of which is the web of entangled rigging and its shadows on the water, is very fascinating. The other two, "The Prow" and "The Rudder," are masterpieces, and yet how simple: the one in which the bow and bowsprit of a large vessel run up the side and top of the picture, and help with the other two parts of the frame to enclose an expanse of water broken in the distance by the dim dock wall and a cloud of steam, is most effective, the interest of the picture being here the part thus enclosed. Contrast this with "The Rudder," very similar in composition, but then the projecting stern of the vessel, the rudder itself, the staging and the men form the point of interest.

We can only congratulate Mr. Coburn on what undoubtedly is his great characteristic, that he is able intuitively to seize points of view in a manner peculiarly his own.

The exhibition will remain open for a fortnight, and it is one which those interested, not only in photography, but art as well, should visit. There are many towns with photographic clubs and societies within easy distance of Liverpool, and we would urge on the members to be sure to visit an exhibition from which so much is to be gained.

C. THURSTON HOLLAND.

## Patent News.

Process patents—applications and specifications are treated in "Photo Mechanical Notes."

The following applications for patents were made between April and 21:—

COLOUR PHOTOGRAPHY.—No. 9,100. Sensitive plate for colour photography. B. J. Mills for La Soci   Anonyme des Plaques et Papiers Photographiques A. Lumiere et ses Fils, Lyons.

TABLE APPARATUS.—No. 9,370. Improvements in portable photographic apparatus, suitable for photographing and reproducing animated scenes. Henri Louis Hurt, 46, Lincoln's Inn Fields, London.

MOVING THE CAMERA.—No. 9,371. Improvements in apparatus for determining the right position of the photographic camera. Alfred Muschke, 16, Hansaring, Cologne.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PHOTOGRAPH COPYING MACHINE.—No. 25,040, 1905. The invention is a machine for carrying out a method of reproducing the tones of a photograph by straight lines, ruled on to paper, the lines varying in width according to the tones of the original. A relief is made of the photograph, and may be reproduced in harder form by electrotyping or stereotyping. It is then fixed on to a movable bed plate, like the bed plate of a planing machine, so that it can be moved to and fro under a fixed pen. Provision may be made, if desired, for lifting the pen on the return stroke of the bed. The paper on which the drawing is to be executed is fixed in position over the relief, and the bed is then drawn under the fixed pen. The pen is adjusted so that

when lightly touching the paper it draws a very fine line, and as the pressure increases, the thickness of the line drawn increases. By moving the bed under the pen and slowly traversing the pen just as is done in a planing machine, we get a reproduction in line of the original subject. The continuous tone of the original subject is thus mechanically broken up into lines of varying widths. It is much better to draw on paper held absolutely flat on the bed of the machine and get the varying breadth of line by causing the relief to travel beneath a stylus at the same time as the paper travels beneath the pen. The varying thickness of the relief communicates a motion to the stylus which is by some means communicated to the pen and

Fig. 1.

causes it to draw a fine or a thick line according to the thickness of the relief at the moment beneath the stylus. In the machine shown in Figs. 1 to 3, the relief image and the drawing paper are fixed side by side on the reciprocating table, a, the paper being on the left hand side and the image on the right hand side (Fig. 1). The table is reciprocated by the rack, b, and geared sector, c, operated from the driving wheel, d, by the connecting rod, e, and crank, f. The pen, g, and style, h, are mounted at the ends of the lever, k, pivoted about a transverse axis in a bracket, l, which slides freely on a transverse bar, m, of square section, a spring, v, being attached to the lever tending to lift the pen from the paper. Near the ends of the bar, m, are fixed brackets, n, n, supporting a transverse screw rod, o, meshing

Fig. 2.

with a screw-threaded hole in the bracket, l; the rod, o, carries at one end a ratchet wheel, p, adapted to engage with a pawl, q, carried on the framework of the machine and caused to press on the ratchet wheel by a spring. The bar, m, is capable of a slight vertical movement, being mounted in vertical slots in the framework of the machine, and is also provided with rollers at its ends engaging with groove cams, r, s, at the sides of the machine. The cam, r, is mounted on the driving shaft and the cam, s, on a supplementary shaft carried in a bracket, t, at the other side of the machine. The driving shaft and supplementary shaft carry gear wheels meshing with gear wheels on a transverse shaft, u, by which motion is communicated to the cam s. The operation of the machine is as follows:—The table a, starting from the right hand side of its travel moves to the left to the position shown in the figures, the image passing under the style and the

drawing paper under the pen, a single line being thus drawn. At the end of the movement of the table to the left, the cams *r*, *s*, lift the transverse bar, *m*, and so, by reason of the spring, *v*, lift the pen from the paper; the table then travels back to the right and at the end of its backward movement, the cams allow the bar, *m*, to descend pressing the pen on to the paper again. The pawl, *q*, during the upward movement of the bar *m*, and rod, *o*, passes over one tooth of the ratchet, *p*, and the downward movement of the bar, *m*, causes the pawl *q*, to turn the ratchet wheel one tooth, thus turning the rod, *o*, and moving the bracket, *l*, transversely. The table then moves to the right again and the operations are repeated. It will be seen that in the above described machine the motion of the stylus alters the pressure of the pen on the paper; I may, however, use a pen consisting of a capillary tube charged with ink, and cause the motion of the stylus to control the flow of the ink either mechanically or electrically as in the syphon recorder or in any other suitable way. This method of reproduction has great advantages in three-colour or multiple-colour reproduction as the paper can be swept under three banks of pens controlled by three different reliefs, and charged with three different inks in three directions making 120 degrees with one another without moving the paper from its bed, thus ensuring register, or, if preferred, the pens may sweep successively over the paper, which remains stationary in three directions making 120 degrees with each other. Edward Russell Clarke, 35, Leinster Gardens, Hyde Park, London, W.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

DAYLIGHT CHANGING. —No. 18,413. Improvements relating to daylight changing for photographic plates, films, etc.: Neue Photographische Gesellschaft.

#### CATALOGUES AND TRADE NOTICES.

The 1906 price list of Messrs. W. Butcher and Sons looks as attractive in its old English binding as any photographic list we can recollect. Its contents are no less special in character as it is limited to Messrs. Butcher's own productions, a description of which, nevertheless, occupies 700 pages. The list is intended primarily for dealers, *vide* the section "Business Cards," in which are detailed the facilities provided by Messrs. Butcher for getting and selling their goods, but it is supplied to amateur applicants for 1s. 6d.

A circular, illustrating fifty patterns of photo-pendants, reaches us from Mr. J. Elliott, Market Place, Nottingham.

A new list of Messrs. Wratten and Wainwright's, Croydon, will be read with interest from the facts which it supplies respecting the firm's new bathed plates and modified "Verichrome" plates; facts bearing on exposure, screens, development, and safe-lights. Sent free.

A very beautiful portfolio of specimens of half-tone and line-engraving comes to our table from Mr. Chas. W. Harness, of 37, Princess Street, Wolverhampton. Mr. Harness photographs for catalogue and book illustration, and undertakes the production of plates of all kinds, from the coarse half-tone for newspaper printing to the set of three or four-colour blocks, of which fine examples are included in the portfolio. A trade price list for engraving work is obtainable from Mr. Harness.

THE Tella Camera Company, 110, Shaftesbury Avenue, London, W., send us their catalogue for the forthcoming season, drawing attention to their system of extended payments, and of acceptance of old apparatus in part payment for new.

THE View Album.—In an Inverness newspaper we see a review of an album of views produced by Mr. J. Porter, photographer, of Aberdeen, from which we may quote as showing the local publicity derivable from a publication of this kind. The pictures, most of them taken from fresh points of view, are sixty-four in number, and cover an area including the town of Inverness—the scenic merits of which are well represented—Culloden Moor, Strathdearn, the Caledonian Canal—an elaborate series—Beaulie, Dingwall, Strathpeffer, the Black Isle, and Nairn district. The street photographs of Inverness are particularly excellent, giving the thoroughfares, as they do, that true aspect of bustle which is always associated with the summer and autumn seasons.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
5.....	Hackney Photographic Society	Trip to Waltham Abbey.
5.....	Aberdeen Photo Art Club	Outing to Bennachie.
5.....	Bristol Photographic Club	Outing to Winterbourne.
5.....	North Middlesex Photo. Soc.	Trip to Epping Forest.
5.....	Chelsea and District Photo. Soc.	Outing to Oxshott.
8.....	Hackney Photo. Society	"Photography by Artificial Light."
8.....	Birmingham Photo. Society	Mr. H. W. Bennett.
8.....	Bristol Photographic Club	Exhibition of Hand Camera Work.
9.....	Leeds Camera Club	Club Meeting at Headquarters.
9.....	Acton Photographic Society	Sale and Exchange of Apparatus.
9.....	Everton Camera Club	Lantern Evening.
9.....	North Middlesex Photo. Soc.	Half Day Outing to Bromborough.
9.....	Cricklewood Photo. Society	"Hampton Court Palace." Mr. J. Munro.
9.....	G.E.R. Mechanics' Institution.	"Focal-Plane Work." Mr. M. Hudson.
10.....	Cardiff Windsor Amat. Ph. Soc.	Social Evening. Lantern Slides and Presentation of Awards in Members' Competitions.
10.....	London and Prov. Photo. Assn.	Plates and Papers for Pictorial Work.
10.....	Richmond Camera Club	"Spectro-Photography and the Making of Light Filters, including Controlling Methods by the Abney Colour Disc."
10.....	Rugby Photographic Society	Mr. T. Thorne Baker, F.C.S.
		Annual General Meeting.
		Amateur Photographer 1905 Prize Slides. Annual General Meeting.

GLASGOW SOUTHERN PHOTOGRAPHIC ASSOCIATION.—The annual general meeting was held in the Club Rooms, 169, Eglinton Street, on Tuesday, April 24, at 8 o'clock p.m., Mr. W. S. Morren, President, in the chair. The financial statement showing a balance of £3 10s. 1d. on the year's working was considered satisfactory. The officers for the ensuing year were elected, as follows:—President, W. H. Wilson; Vice-President, Robert Wallace; Secretary, Charles Young, 217, Crown Road, Partick; Treasurer, E. J. Grant; Librarian, R. Lindsay; Council, J. Pollock, A. Neilson, R. Ure, W. S. Morren, Miss M. Somerville, and Miss E. Miller; Delegates to the Scottish Photographic Federation, the President, Vice-President, and Secretary. The outings for the summer programme were also arranged.

ROTTERHAM PHOTOGRAPHIC SOCIETY.—The Page-Croft pigmen paper was demonstrated to the members at the meeting held on April 20. The case of manipulation and the delicacy of the finished prints proved not the least of its recommendations. Mr. C. E. Davis, assistant secretary, in a subsequent address on "Plate Developing for Beginners," urged the importance of cleanliness of apparatus and carefulness in the use of approved formulae.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At a recent meeting, Mr. F. J. Mortimer, F.R.P.S., gave a lecture on wave photography of a very educative character. As to the lens, the better the quality the better the work should be, but as the lens generally had to be stopped down to *f*/16, a good rapid rectilinear should give as fine a picture as most were likely to require. As a guide to exposure, 1000 of a second at *f*/16 in good April sunlight, and a plate about 200 H and D. should give a properly exposed plate. From much experience he considered the roller-blind shutter working in front of the lens was the best type, though on dull days a focal plane shutter would be of value. Wave photography was not meant for the butterfly amateur, as one had to run many risks of life and limb. Sea boots and oilskins must be worn, and the camera must be well protected, rather than the salt spray would ruin the metal parts in a week. In attempting to capture the big breaking roller it was well to have a companion at the end of a stout rope. As the power of the light was much the same for sea and sky, the exposure given fits both, so that clouds and sea are usually rendered on the same plate. A little foreground generally improved the picture, though composition had rather to be chanced. Development should be with a dilute and clean working developer, and stand development was very suitable.

A GOOD SUMMER PROGRAMME.—The Bristol Photographic Club have just issued their programme for the first two months of the summer season. Excursions are arranged for every Saturday afternoon and every Wednesday evening, while once a month there is a technical night at headquarters. Certain of the outings will be specially devoted to giving practical help to beginners in the field, and the monthly meetings are to afford a continuation of this.

struction in the subsequent operations of development, printing, etc.

**THE BRISTOL PHOTOGRAPHIC CLUB.**—At the annual general meeting held last week, Mr. John Fisher in the chair, the following officers were elected:—President, John Fisher, Esq., Hon. A.R.C.A. don; vice-presidents, Mr. M. B. Fowler, F.C.S., Mr. H. R. Ford, Mr. J. Steger, B.Sc.; council, Messrs. T. W. Brown, A. E. ns, H. Goodenough, J. S. Guthrie, F. Little, and W. W. Smith; secretary, Mr. George Easonsmith, Central Printing Works, St. John's Street; hon. treasurer, Mr. E. Beaven; hon. folio secretary, Mr. R. W. Coates; hon. reporter, Mr. M. B. Fowler, F.C.S.

**THE HULL PHOTOGRAPHIC SOCIETY** opened their summer programme visiting Thornton Abbey last week. The abbey claimed the test attention, and knowing that there is to be a comparison of work done at the monthly meeting next Thursday, great care was exercised in securing the best points of view. The next outing is to Beverley and its Minster on May 12.

**LYTON PHOTOGRAPHIC CLUB.**—The winter series of weekly lectures and demonstrations were brought to a close on Friday, April 27, with an address by the chairman, Mr. Hector Maclean, F.R.P.S., on "Types of Hand Cameras." The subject, to which over an hour and a half was devoted by the lecturer, was illustrated by means of a large assemblage of representative hand cameras. A good deal of information imparted was of necessity elementary, but one or two points deserve recording. One was the statement that an "instant" hand camera should be provided with two distinct types of view-finders. Of these, one should be of the form which shows a small replica of the scene or subject which the photographer is looking down upon, such as is found in the so-called "brilliant" view-finders; while the other should take the shape of the "direct" view-finder pattern, such as is usually fitted to a focal plane camera. The other matter enlarged upon related to the diaphragm shutter, and, although indicating a range of four or more snapshot exposures, was often virtually a one-speed shutter. In this connection he outlined the advantages of a new pattern shutter in which the shutter speed, instead of being "regulated" by a friction of a pneumatic brake, was varied by altering the size of the opening in the shutter blades, much as is done with the slit of a focal plane shutter. Another promising adjunct to hand cameras which he mentioned and explained was a new type of moderate power telephoto lens, which, no larger than an ordinary R.R., gave an image of dimensions equivalent to those attainable with a lens of 10in. focus, in a camera extension of only 5in.; the working aperture is  $f/9$ , the name of the lens "Bis-telar." The one shown was fitted to an ordinary 4-plate roll-film camera of about the dimensions of a 3.5 F.P.K.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Mr. H. T. Malby favoured the above Association with a visit on the 26th ult., his lecture being in the chair. Mr. Malby's subject was a collection of lantern slides, and over a hundred of the best class of slides were shown. The first series was one taken at Mr. Malby's home, just upon the borders of Epping Forest. The lecturer said that much as Epping was decreed, there was a really fine photographic work to be done there at all seasons of the year. Mr. Malby next treated child life in the poorer parts of London and other large cities, saying that when working in the slums, it was almost impossible to obtain more than one shot per day in any one street, as the youngsters, immediately they discovered what was about, were off like wild rabbits.—(Eds.) Cloud studies were shown, most of them being in series of three to seven, taken at intervals of three minutes, the change in the formation being very marked. A series taken by the aid of a specially bent glass distorting mirror caused great amusement, some of the effects being very funny for words. Flower studies, Mr. Malby's favourite work, included the series, and in this connection the lecturer said it was imperative to have the same foliage as the flowers. He also insisted on the use of orthochromatic plates and screens for this class of work. Mr. Teape, referring to the distortion slides, asked where such mirrors could be obtained. Mr. Malby said the mirror was an expensive item, as it had both horizontal and vertical distortions. In fact, it had cost some £80 to make, though he thought that one having been made others could be done somewhat cheaper.

**MIDDLESEX PHOTOGRAPHIC SOCIETY.**—Bromide enlarging

was the subject of a lecture by Mr. H. W. Fincham on the 18th inst. A practical demonstration by means of a lantern and incandescent gaslight enhanced its value materially. A number of negatives of medium to thin density were projected on the screen, and, with a stop value  $f/11$ , the exposure required, enlarging from 4 to whole on rapid bromide paper, was about 30 seconds. For those who worked with films, the lecturer showed a method of focussing by means of a piece of veiling net sandwiched between two pieces negative glass. Amidol was recommended as a developer and made up as follows: Sulphite of soda, 1oz.; citric acid, 20 grains; bromide of potassium, 15 grains; water, 20oz. Take 3 grains of amidol and dissolve in 1oz. of water, and then add 1oz. of the above sulphite solution.

**CHELSEA AND DISTRICT PHOTOGRAPHIC SOCIETY.**—At a meeting held on April 19, 1906, at Public Library, Manresa Road, Mr. A. G. Mountford lectured on "Flashlight Simplified." He explained that he used argentine powder as, owing to its fineness, it fires quickly, practically instantaneously, and very little was needed to secure a good flash. Spread the powder in a line from 2ft. to 3ft. long—the longer the better, as good diffusion and soft lighting will thereby be secured. He recommended firing the powder by a spark from a small induction coil supplied with current from a small accumulator. The whole outfit would be obtained for considerably less than a pound.

## Commercial & Legal Intelligence.

THE statement of affairs in the estate of Eleanor Keene, of 52, High Street, Burton, photographer and widow, has been issued. The gross liabilities are £200 12s. 8d., of which £162 5s. 2d. is expected to rank for dividend, and there is a deficiency of £103 10s. 2d. Debtor states the cause of her failure to be slackness of trade, heavy working expenses, and keen competition, and she anticipated a deficiency of £141 17s. 8d. According to the Official Receiver's report, the bankrupt states: (a) That she carried on the business of a photographer, formerly carried on by her husband; (b) That she continued the business on his death, although she was advised by her solicitors that the business was insolvent; that she believes her husband's liabilities at his death were about £300, and his assets about the same amount as in the present statement; (c) That her husband, by his will, left her all his estate, but she has not proved the will, he being insolvent; (d) That she was frequently sued by creditors, and that twice within the past six months certain of her goods were seized under small executions; (e) That the only books are a rough cash book and a day book, that she became aware of her insolvency twelve months ago, or probably longer, and thinks she has been trading at a loss for some time past.

THE first meeting of creditors was held on April 19 of the Birmingham and District National Trading Company, Norwich Union Chambers. The statement of affairs showed liabilities £146. The meeting was adjourned until April 27.

**A LIKENESS CASE.**—At the City of London Court, on April 26, Mr. Aaron Lissack, 46, London Wall, claimed 19s. from Messrs Emberson and Son, photographers, 62, Cheapside, money paid for a photograph. Plaintiff said that the photograph was inaccurate and the workmanship bad. Defendants said that the photograph had been approved by the plaintiff, and was quite satisfactory. Plaintiff said his face was blurred. The Judge found for the defendants, with costs.

**THE SALE OF A BUSINESS.**—At the City of London Police Court, on April 26, Messrs. Taylor, photographers, Queen Victoria Street, claimed £8 10s. and £3 14s., in two actions, from Mr. H. J. Blount, 63, London Road, Derby, as damages for breach of contract. It seemed that the plaintiffs disposed of their business at Derby to the defendant under a contract which said, "All orders taken by the vendors during the last twelve months and those on the books at this date which are incomplete shall be taken over and executed by the purchaser." The defendant refused to fulfil some of the orders, and as a result the plaintiffs were sued for the return of the deposits. The plaintiffs now claimed those sums as damages for breach of contract. The defendant said that the plaintiffs had no business to pay the money claimed. The Judge found for the defendants in both cases, with costs.

In the Birmingham Court of Bankruptcy, on April 27, Mr. Registrar Whitelock made a receiving order in the matter of Arthur Henry Seeley Draycott and John Arthur Draycott, of 64 and 65, New Street, and 138, The Parade, Leamington, photographers and art dealers, trading as The Draycott Galleries. Mr. Walter J. Rabnett is solicitor in the proceedings.

**PHOTOGRAPHIC JOURNALISM.**—At the City of London Court, on April 26, Mr. C. F. W. Sage, 16A, Bouverie Street, E.C., sued the "Daily Express," Limited, for £19 as damages for breach of contract. Mr. Turner appeared for the defendants. Plaintiff said that in July he was employed by the defendants to "get out" their photographic page. He was to be paid a salary of £3 a week for six months. That was paid to him for six months, but the arrangement had been terminated. There was, however, he maintained, a conversation to the effect that he was to be paid a commission on a scheme for selling pictures to other papers, and his case was that the defendants had broken the contract. The defendants were not called upon, the Judge remarking that no case had been made out.

**SUNDAY Trading.**—Walter Charles Cork, a Bradford photographer; Arthur Bell and Elizabeth Perry, confectioners, of Baildon, were summoned at the Otley Police Court on April 27 for Sunday trading at Baildon. Cork sent a postal order for 5s.—the maximum penalty—to the superintendent of police, and asked for an acknowledgment. Cork was fined 5s., including costs, and Bell and Perry 2s. 6d., including costs.

**GUNN AND CO., LIMITED** (Photographers, London).—Issue on March 22 of £300 5 per cent. debentures, part of a series created November 29, 1904, to secure £1,000, charged on the company's property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £700.

**ENLARGEMENT Fraud.**—Last week, at Bolton, Robert Francis Demmock, photographer, of Accrington, was sent to prison for three months for obtaining a shilling by false pretence from a lady. He obtained the money on the pretence of enlarging a photograph.

**A POISON SUMMONS.**—John Smith, a Harrow watchmaker, was summoned at Edgware last week for selling a photographic intensifying solution containing 40 grains of corrosive sublimate without labelling the bottle "poison." A science master at Harrow recently found in the possession of one of his pupils a bottle of the intensifier not labelled poison. He communicated with the Pharmaceutical Society. Mr. W. S. Glyn-Jones appeared for the Pharmaceutical Society, and defendant, who pleaded that he sold the article as received by him, was fined 5s. and 8s. 6d. costs.

**A TRIUMPH of Diction.**—We are pleased to see the laudable measures taken by our contemporary, "The Amateur Photographer," to educate and improve the photographic novice. The offer is now being made of a plaque (designed in Glasgow), replicas of which in silver and bronze are to be awarded in a series of beginners' competitions. The design of the plaque is described by our contemporary in the following passage, which is, perhaps, as beautiful a thing in its way as any writing on art in photography which we have had the pleasure of perusing:—

*"The subject represents Photography seated at the feet of Art, having laid down for the moment she too must go, where, above the liar to her craft, whilst her sister points the way the camera and other appliances peecutemple of knowledge, the sun shines."*

It must be difficult to imagine the merit of a photographic work which deserves an award answering to the above description.

**"R. A. P."**—A writer from a southern seaside resort informs us that a photographer practising there possesses, as an appendage to his name, the initials, "R. A. P." We are unable to say what precise diploma these letters denote, though it may be stated that in view of the close prices charged for the photographer's productions—six photographs on a postcard for 1s. 9d.—the other photographers in the town may be pleased to anticipate "R.I.P." as a correct title.

THE full programme of tours in Holland and Germany, conducted by Mr. W. F. Slater, has now been published, and can be obtained from him at 86, Longhurst Road, Lee, S.E. To those desiring a photographic holiday, relieved of all the cares of travel, the tours organised by Mr. Slater can be heartily commended.

## Dews and Notes.

**ADHESIVE Dry Mounting Company, Limited, v. The Adherent Film Company.**—In Mr. Justice Kekewich's Court, in the Chancery Division, counsel, on April 11, said he had a motion on behalf of the plaintiff company in an action brought by them against the defendant company for alleged infringement of two letters patent. It had been arranged, with his Lordship's sanction, that the motion should stand over until Monday, April 30. Mr. Justice Kekewich assented.

**DARK Rooms for Tourists.**—The editors of the "Photographic Monthly" ("The Photogram") notify us that they have in preparation the fifth annual directory of dark rooms available for tourists throughout the world. They invite owners of dark rooms who may

WHERE THIS SIGN IS SEEN A DARK ROOM IS PROVIDED FOR THE USE OF TOURISTS. A LIST OF SUCH DARK ROOMS ALL OVER THE WORLD IS PUBLISHED BY THE EDITORS OF THE PHOTOGRAPHIC MONTHLY 6 FARRINGTON AVENUE S.E. LONDON E.C. AND A COPY MAY BE SEEN WITHIN.

not be included to apply to them for entry in the directory. To favour, a copy of the directory itself, and copies of the dark-room sign, shown on a reduced scale herewith, are offered free of charge to those who will undertake to keep the sign displayed and the directory available for reference.

**A CELLULOID Accident.**—Mr. J. W. Wakelin, of Braintree, writes to the daily papers as follows:—My daughter was sitting writing near a lamp, when a comb made of celluloid caught fire. As a result it burnt nearly all her hair off, and simply roasted her scalp, causing awful agony. But for the unremitting attention of two doctors and a hospital nurse, my daughter would undoubtedly have lost her eyesight, if not her life. In the interest of suffering humanity I am making this public in the hope that something may be done either to stop the sale of, or, at least, to stamp as "inflammable" these articles, so that the public may know what they are purchasing. My daughter had not the least idea that she was buying a dangerous article when she bought the comb.

**THE Late Mr. Arthur Holborn.**—We regret to announce the death after a short illness, of Mr. Arthur Holborn, of Graphic House, Stokes Croft, Bristol. Mr. Holborn, as a photographer, has been well known in Bristol for more than forty years. He has also, in former years, branches at Thornbury and other places. Mr. Holborn was a Freemason, being a member of the Moira Lodge. His excellent personal qualities were generally recognised, and the announcement of his death will occasion a wide feeling of regret and deep sympathy for his widow and family.

**ROYAL INSTITUTION.**—At the annual meeting, held on May 1, following gentlemen were unanimously elected as officers for the ensuing year:—President—The Duke of Northumberland; treasurer—Sir James Crichton-Browne; secretary—Sir William Crooke; managers—Sir William de W. Abney, the Right Hon. Lord Alton, the Right Hon. Earl Cathcart, Dr. A. H. Church, Dr. Elgar, Dr. D. W. C. Hood, Mr. M. Horner, Sir William Huggins, the Right Hon. Lord Kelvin, Mr. H. F. Makins, Dr. Ludwig Moir, Sir R. Douglas Powell, Bart., the Right Hon. Lord Sanderson, Mr. Alexander Siemens, and the Right Hon. Sir John Stirling; visitors—Dr. J. Mitchell Bruce, Mr. Dugald Clerk, Sir John George Craggs, Mr. H. Cunynghame, Mr. G. F. Deacon, Mr. E. Dey, Rev. J. H. Ellis, Mr. R. K. Gray, Mr. C. E. Groves, Mr. F. Henriques, Mr. A. C. Ionides, Mr. C. E. Melchers, Mr. E. Merton, Mr. H. Swithinbank, and Mr. G. P. Willoughby.

SERIES of summer courses are announced as just commencing at the Manchester Municipal School of Technology. Three are on engravings, portraiture, and printing processes; whilst a fourth treats of a branch of work in which we are glad to see systematic instructions being given, viz., catalogue illustration. The lecturer is Mr. W. H. Wainwright, and the syllabus includes:—"General arrangement and design in relation to the subject matter. The typography and press-work suitable for different methods of illustration. Cover design. The photography of different objects, as machinery, furnishings, garments, millinery. The preparation of drawings and the printing of photographs for 'process' reproduction. The methods of reproduction, line, half-tone, tri-colour and collotype printing. The printing and binding of catalogues. A small catalogue will be prepared during the course as an example." We should like to see the designing and carrying out of photographic advertisements receive special attention in the schools of photography. It is a very remunerative branch of photography, pursued at present by a comparatively few men, who naturally see no reason to talk about

the suicide of a photographer named Abraham Booth, aged fifty-one, of West End, Stapleford, occurred last week. According to the evidence at the inquest, the deceased drank some of the chemicals in his business, and died shortly afterwards.

THERE is now on exhibition in the Art Gallery at Kingston a photographic panorama of San Francisco, by the late Edward Muybridge. It consists of thirteen prints, each 16in. by 22in., and is a very fine piece of photography. It is probably the only copy in this country. "Photography Simplified" is the heading to a series of chapters arranged in the "Queen" by Mr. Snowden Ward, with illustrations by Mrs. Catharine Weed Ward. The first instalment deals with printing as the simplest introduction to photography.

THE Photographic Society.—In addition to the paper to be read by Mr. H. J. Channon on May 8, a demonstration of a new self-developing paper will be given by Messrs. John J. Griffin and Sons, Ltd., of Glasgow. Scottish Federation.—Sir John Ure Primrose, Bart., LL.D., has been elected to the presidency. He is connected with at least a dozen different societies, the Glasgow Southern Ph.A. and the Glasgow Amateur Ph. A., and is an ardent photographer. His retirement in connection with the opening of The Salon at Glasgow, even though he is labouring under the multifarious duties pertaining to the Lord Provost of Glasgow, are probably not forgotten by the Federation. What is freed from his civic duties, he is taking a more active personal interest in the work of the societies.

THE Kodak Travelling Exhibition is now making a tour in the northern parts of England. The following are the places to be visited on the occasion, and the dates during which the exhibition remains:—Huddersfield, April 23, 27; Southport, April 30, May 4; Preston, May 7, 11; Burnley, May 14, 18; Burnley, May 21, 25; Darlington, May 28, June 1; York, June 5, 9; Darlington, June 12, 16; Leeds, June 19, 23.

## Correspondence.

*Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given. We do not undertake responsibility for the opinions expressed by our correspondents.*

### INTENSIFICATION BY THE CHROMIUM PROCESS.

To the Editors.

GENTLEMEN,—I am afraid that Mr. Thorne Baker, in his series of papers on "The Theory and Practice of Intensification," has gone far astray in his explanations of the theory of the chromium process. This method of intensification was very carefully investigated by Mr. D. J. Carnegie and myself a year or so ago, hence I am able to speak positively with regard to matters that Mr. Baker has treated from very speculative points of view. In his second article it is stated that "the 'bleached' image, after

washing, may be re-developed with an alkaline reducing solution, when certain chromium compounds are precipitated upon the original silver and sub-haloid image, thus giving very considerable intensification to the negative." And also that "the redeveloper quickly decomposes the precipitated chromate, with the result that oxides of chromium adhere to the silver particles, and cause the intensification." I cannot understand what Mr. Baker had in mind when he referred to "precipitated chromate," and these two separate explanations are not exactly in accord with each other, while neither is anywhere near the truth. The chromium compound, which is a brown oxide, is formed during the act of bleaching the image, and the agent responsible for its reduction from the bleaching solution is the original silver of the image. The developer plays no part in the production of the compound, and has very little subsequent effect upon it. It reduces it to a lower oxide, but this effect is very partial and almost imperceptible in the case of an image containing both silver and oxide, though if the brown oxide is isolated it is speedily reduced to chromic oxide by any developer.

We are also told that the chromium oxides are precipitated between the granules of silver, and that "very small, if any, interaction takes place between the chromium oxides and the reduced silver particles." This statement is made on no better evidence than that afforded by examination under the microscope, which would not be likely to reveal such conditions, even if its magnification somewhat exceeded 1,200 diameters. The more rational test of analysis will soon show that the oxide is not simply precipitated between the granules, but is so intimately associated with the silver that the two substances cannot readily be separated. There is, no doubt, a definite molecular relationship between the quantities of original silver and reduced oxide, though the proportion of the latter that remains in the image is materially affected by the fact of its reduction taking place in an acid solvent solution. There is not likely to be any interaction between the oxide and the reduced silver, but it is just possible that some loose chemical combination exists between the silver and the chromium compounds produced in the bleaching process. This point, however, we could not settle definitely. Mr. Baker gives figures from which he assumes that intensification is greater in the under-exposed than in the well-exposed parts of the image; but this assumption is not warranted by his figures, which show that the highest density has received exactly the same intensification as the fog strip. In the lowest two and in the highest strips the intensification is practically equal, and the falling off in the second and third strips suggests only an experimental error.

With regard to the practical application of the process it would be interesting to know why Mr. Baker assumed that the use of calcium chromate would accelerate the action, and why in his list of "modern" formulæ he uses potassium chromate instead of the bichromate. I think it has before been pointed out to him in your columns that the use of chromate is only an undesirable and expensive way of arriving at the same result as that obtained with the bichromate, which is certainly the salt used in most "modern" formulæ. I must also point out that the developer he gives (hydroquinone and caustic soda) is the least desirable out of the many available. It is slow in its action and often leads to frilling and also to slight staining if the development is prolonged and carried out in bright light. Sodium carbonate is the safest alkali to use, but it is best to avoid alkaline developers and use amidol.

With regard to the permanganate process, I experimented with this about two years ago, and came to a conclusion quite opposed to that of Mr. Thorne Baker. The solution, even when fresh, generally decomposed spontaneously, and deposited a manganese compound indiscriminately over the over film, and in the few cases in which I obtained clean results there was practically no useful intensification; no more than can be produced by many processes of simple redevelopment involving no metallic addition to the image. Mr. Baker claims very great intensification in the case of negatives, though his measurements show an almost negligible amount in the case of experimental strips. This suggests only that the photometer is a better judge of density than is the human eye. For some not very obvious reason he recommends two entirely different formulæ for the permanganate process in Chapters II. and III.

With regard to mercurial intensification, the statement that sodium sulphite does not re-blacken the image but produces a brown colour-

abstract of Messrs. Carnegie's and Piper's papers, which originally appeared in "Amateur Photographer," is given in the BRITISH JOURNAL ALMANAC, 1904.—Eds. B.J.P.

ation is not in accord with my experience, for at one time I specially favoured this particular process for negatives on account of the clean black images that I obtained with it. It is strange that the only really reliable mercurial process, mercury and ferrous oxalate, has not even been referred to. Mr. Baker mentions in his first article, as a recent method of intensification, "the conversion of the silver into a haloid, which will darken on exposure to light." It would be interesting to know of such a process, but I never yet met with it. Though I have frequently used such methods for diminishing density, I am not acquainted with one that increases it.—Yours, etc.,

Blackheath, April 28, 1906.

C. WELBORNE PIPER.

#### BLEACHING BROMIDES.

To the Editors.

Gentlemen,—Your correspondence on sepia toning interests me, and I may perhaps be allowed to submit a few notes, at the same time preserving brevity.

Experience in this direction began for me in January, when two enlargements of views from Epping Forest were toned, and proved successful such that they now hang framed in a study. Since then I have thus treated some dozen pictures, ringing the changes on the extent of bleaching, and hence the depth of tone in a finished print. The fact remains, however, and it appears to support the truth of Mr. Allen's inference that the prints are invariably dried previous to toning, although soaking is occasionally resorted to in order to flatten the photographs under treatment and ensure even bleaching.

My pet formula, if citing another will aid in solving the problem, is (for any picture up to 12in. by 10in.):  $\frac{1}{2}$  oz. 10 per cent. solution potass bromide,  $\frac{1}{2}$  oz. 10 per cent. solution potass. ferricyanide, water to the least possible workable amount, wash for five to ten minutes, after bleaching to the extent desired, and redevelop in sodium sulphide 5 per cent. solution.

With assurances that I esteem your paper in not for ever dosing its readers with "How to develop" or "Why P.O.P. is toned," subjects which seem to be enjoying a term of publicity in modern journals.—I beg to remain, yours truly,

STANLEY BARNARD.

12, Queen's Road, Ilford.

April 28, 1906.

#### THE RECENT COPYRIGHT CASE.

To the Editors.

Gentlemen,—The copyright decision of Mr. Justice Farwell mentioned in your columns opens up many possibilities to those who think that photographers, like railway companies, are food for plunder. If an owner of any show place in a neighbourhood gives permission to a photographer to take a series of views, as owner of the copyright there is nothing now to stop him selling or transferring the same to anyone and thus rob the author of the whole fruits of his skill. I hope the profession will support an appeal against this decision. At time of writing I have a similar case on hand.—Yours faithfully,

F. NEWELL.

Manningtree, Essex.

#### MEASURING SHUTTER SPEEDS.

To the Editors.

Gentlemen,—I see that you are publishing in your next issue an article on the pendulum, and should be glad if you could find space for this letter, which endeavours to clear up the controversy over Mr. Watkins's method of testing shutter speeds. It appeared to me to be commercially sound and useful, and I wrote to you on the 3rd inst., as I wished to test its accuracy mathematically, and was unable to do so with your formula  $\frac{s-w}{2\theta\sqrt{2l}}$

It will be within the recollection of your readers that the method Mr. Watkins adopts is to fix the camera on the upper member of a compound pendulum to compare the short dashes on the plate, obtained by photographing the sun at different shutter speeds, with the base line traced across the plate by the sun in one second of time—i.e., in one swing of the pendulum.

Your correspondents seem well up in the theory of the pendulum, but none of them have applied their formulæ to the specific case given by Mr. Watkins in your issue of the 30th ult., where the base-line was 93.9 mm., representing one second, and the dash for

the exposure 4.2 mm., both less 1.1 mm., the diameter of the sun. The length of the corresponding simple pendulum 994 mm., and the total angle of swing 40deg. 15min. Time of exposure is stated to be 1.47th of a second and a small fraction by three methods.

The following proof may be interesting, showing that the above shutter speed is correct, that "the underlying principles are sound, and that it is capable of giving results of as high a degree of accuracy as there is need for," to quote your correspondent, Mr. Carnegie.

The dashes show by their length the angles through which the camera swings while the shutter is open, and these angles may be read directly by an evenly divided scale, whatever part of the plate they fall upon, but are longest and least liable to error if read at the middle of the plate; but I will adhere to Mr. Watkins's figure.

The velocity of the pendulum at midswing is given by  $V = \sqrt{2gh}$  or by  $2\theta\sqrt{2l}$  in your formula, and equals 3.58 ft. (1,094 mm.) per second.

$\frac{h}{l}$  = the versine of half the angle, and  $l$  the length of the simple pendulum  $\theta = 40^\circ 15'$  min.

The circumference of the circle of which  $l$  is the radius =  $9\pi \times 3.1416 \times 2 = 6245$  mm. The travel of the bob in one second

$$\frac{40^\circ 15'}{360} \times 6245 = 698 \text{ mm. } (\theta l = 994 \times .702)$$

The dash given by the exposure is to the travel of the bob during the exposure as the base line on the plate is to the total swing of the bob:— $3.1 : \pi :: 92.8 : 698$ .

The travel during exposure  $\pi = 23.3$  mm. (.076ft.), which  $\div 10$  the velocity per second, gives the exposure as 1.47th of a second.

By your formula corrected

$$\frac{s-w}{2\theta\sqrt{2l}} = \frac{.076\text{ft.}}{2 \times .702 \times 2.553} = \frac{.076}{3.587}$$

the exposure is also 1.47th of a second, so that in both ways we get the same result as Mr. Watkins. I give the result by your formula as it will appear more convincing, but I may add that it compares two things that have no direct relationship, nor you say in your editorial note that all dimensions must be taken in feet. If used as stated by you the exposure would

$\frac{3.1}{1094} = \frac{1}{354}$  th of a second. The sun does not travel over the plate

3.58 ft. a second, but at .453 ft.

Your formula should read  $\frac{(s-w) 7.5}{2\theta\sqrt{2l} \times 305}$  I take 7.5 to be the

ratio of the two members of the compound pendulum, and 305 (millimetres in one foot) to bring the factors to the same units. It was this discrepancy that occasioned my first letter.

I have arrived at these figures without reference to Mr. Watkins but I hope they may be of assistance to him.—I am, Gentlemen, your obedient servant,

C. J. BOSANQUET.

Claverley, Blackheath Park, S.E., April 20, 1906.

#### PHOTOGRAPHIC TERMINOLOGY.

To the Editors.

Gentlemen,—In the second of Mr. T. Thorne Bakers' articles the "Theory and Practice of Intensification" (B.J., April 13, 1906, p. 284) the "readings" of some H. and D. strips before and subsequent to intensification are given. Both from the context and the former article, as well as the curves, one would gather that the readings were to be considered as "densities" in the sense proposed by Hurter and Driffield and since standardised in sensitometric usage—namely, the common logarithms of the opacities—i.e.,

$$D = \log_{10} O = \log_{10} \frac{I_0}{I}$$

where  $I$  is the intensity transmitted,  $I_0$  the intensity incident. But the numbers given are of a magnitude quite inconsistent with this view, a density of 4 to 5 (H. and D.) being the utmost measurable, whereas Mr. Baker's readings go up to 19.8. Are they H. and D. densities multiplied by ten? For the sake of clearness, and the interest of the standardisation of sensitometric quantities, I think it would be well if this point were made more definite.

Catford, S.E.

S. E. SHEPPARD.

# Answers to Correspondents.

*Matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

*Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 1, Wellington Street, Strand, London, W.C.*

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

## PHOTOGRAPHS REGISTERED:—

Essex, 59, London Road, Liverpool. Photograph of Jack Taylor and Sandy Young, Everton Football Club, Shaking Hands, with the English Cup in front on Table. Photograph of Jack Taylor, Captain, Holding the Cup. Photograph of Jack Taylor, Mr. Bainbridge, and Sandy Young, Standing, with Cup on Table. Photograph of Jack Taylor and Sandy Young, Everton Football Club, with English Cup.

Worthy, 169, Park Road, Oldham. Photograph of a Tram Car being used at a Wedding Equipage.

Essex, 8, Gainsboro' Street, Sudbury, Suffolk. Photograph of Sir C. Bart.

Wicks, 4, Springfield Road, Brighton, Sussex. Two Photographs of the vessel in the Church of St. Mary, Newick, Sussex.

Wicks, 41, Mosley Street, Barnoldswick, Yorkshire. Photograph of F. C. M.

Lees, 28, Corporation Street, Manchester. Photograph entitled, "An 1st at Work."

**AS STRETCHERS.**—Kindly give the name and address of maker or dealers in the cheap canvas stretchers now used for 20 x 16 romide enlargements. Some time ago I saw an advertisement in the B.J.P. of a firm advertising them for sale, but not having the back numbers am unable to trace it.—J. H.

Griffiths Steam Works, 26 to 31, Eyre Street Hill, Hatton Garden, London, E.C.

**ING.**—I have been a printer for some years and have not had much printing-in to do. Could you give me a few hints as to how to go about it, both as to printing-in and printing-up of sizes?—J. B. BERTRAM.

We cannot answer your query usefully in the space available in this column. You should get a text book, such as Burton's "Photographic Printing Processes" (Marion and Co.), containing instructions.

**K.**—1. There is none. 2. You can purchase sensitised albumen paper which will keep for a reasonable time. Messrs. Griffin are makers of such a paper.

**O.**—I should be much obliged by your kind advice on the following matter. A room, facing east, 40ft. long by about 7ft. wide, and 8ft. 4in. high, could have two of its windows thrown together, making glass 12ft. long and right up to the ceiling with about 2ft. at the floor unglazed. Can satisfactory pictures be obtained in such a room as a studio—single figures, children, and groups? It is not possible to let light in on the top, as there are rooms above.—T. R.

Although the room will not really make an ideal studio, it will make one in which excellent work can be done, with but little trouble in the working. In making the alterations, we should recommend that the glass be carried up as high as is possible.

**STION MAKING.**—I have lately—i.e., for the last five months—been attempting the manufacture of my own process of lantern slides. A certain amount of success has attended these efforts, but I am desirous of getting a few hints about the principle of long and short scales of gradation, and how much combined silver is really necessary; also, how speed varies with heat, and whether a prolonged gentle heat is preferable to a shorter time at higher temperatures. If you could introduce me to any literature or articles in back journals, dealing with such technical points, I should feel greatly obliged.—S. B.

One must go back practically about twenty years to find any series of articles on emulsion making in our pages. Possibly our querist might obtain, second-hand, a copy of Abney's

"Photography with Emulsions," or, if he can read German, Eder's "Handbook" (Vol. III.) would be of very great value to him. As a rule, a longer scale of gradation is obtained with increase of proportion of iodide in the emulsion, and also by reducing the amount of gelatine during mixing. As to the amount of combined silver, this, of course, varies with the speed of the emulsion, but 1½ grains of silver haloids to the quarter-plate is ample. We do not understand why our querist should want to know about speed if he only desires to make lantern and process emulsions, because speed hardly comes into play. Still, long-continued gentle heat is better than short high temperatures.

**PULLIGNY LENS.**—I shall be glad if you will inform me through your correspondence column of a simple means of obtaining the necessary correction of camera extension to secure sharpness with a Pulligny anachromatic single lens. I have purchased some lenses unmounted, from the makers, and although I can obtain a very fair result by racking in a trifle after focussing, I should like to know if any other more accurate means can be used. Could a coloured screen be used in focussing which would be removed on exposure?—F. E. H.

The correction for the non-coincidence of the actinic and visual foci, as it is usually called, may be very easily made by racking the lens and focussing screen towards one another by about one fifty-fourth of the extension of the camera. In their work on these lenses, MM. Pulligny and Puyo state that one blue-violet screen, as used for three-colour work, is hardly sufficient to give enough correction, and that two such screens make the focussing a matter of difficulty, owing to the great absorption of light. It is also possible to fit on the front of the lens tube a supplementary lens, or "bonnette," and these the makers will supply.

**W. HILL.**—You will find reliable formulæ on page 971 of the "Almanac" for 1906.

**H. EDWARDS.**—There is no such work in existence in English. Abney's "Photography with Emulsions," which has long been out of print, is the only one that is at all likely to be useful.

**INQUIRER.**—1. Is it out of the question to get a satisfactory group of 600 on 12 x 10 plate? 2. Would white paint be satisfactory to subdue light on studio clear glass, which is north light, or can you suggest something? Also, what colour blinds?

1. We should say it certainly is too large a number. We should advise you to take the group on two or more plates, and from them make combination prints or negatives, as recently directed in these pages. 2. We should consider the paint too opaque; better to use starch paste for temporarily obscuring the glass. You may use white blinds.

**ROYAL STANDARD.**—You are at perfect liberty to do as you like with your photographs. The fact of the view point being on private property does not affect the case.

**LIABILITY FOR RATES.**—Will you kindly answer the following, thanking you in anticipation? I took premises at £50 per annum (rates, etc. extra) for one year expiring March 25, 1907. Since I came my wife has been very unwell, and I learn the place does not suit her. If I leave the house, say, in a month, or at a later date, can they compel me to pay the rates, etc., for the remainder of the term if I hand over the keys to the landlord or agent?—C. WHITE.

You will be liable for the rates only during your occupancy of the premises, and not for the full year.

**DAMAGED NEGATIVE.**—I shall be glad of your advice on the following subject: A traveller called on me for an order for enlargements. I gave him an order and handed him a half-plate negative, the firm acknowledging the order, and asking for a guide print. I sent one, but it was a very poor one, although it served as a guide. The enlargement came home, and it occurred to me not as it should be, so I wrote off for the negative. The firm sent me a copy negative from the poor print. I wrote asking for the original. They told me it was damaged through the post. I told them that under the circumstances I could not accept the enlargement, as it was from a copy and not original, and was not, in consequence, what it should be, and asked them what they were going to do. They wrote regretting the accident to the negative, and offered

to make another enlargement, and hoped that would meet my view. Now what I wish to know is, am I bound to accept another enlargement (by the way, as it cannot now be made from the original it cannot be improved upon) or any at all, and as I did not send the negative through the post, can I claim compensation for the damaged negative? I forgot to add that the firm has written me that "no one regrets the accident more than we do, but we are not responsible for damage done in transit." Let it be understood I gave the negative to the traveller of the firm.—T. H. H.

According to a well-recognised "custom of trade," those executing an order are not responsible for damage to negatives in transit or during the execution of orders. An accident has unfortunately happened, and the firm have offered to make all the recompense that can reasonably be expected from them. Of course, the thing is annoying to you, but accidents, at times, are unavoidable.

**BOLD PRINTS ON P.O.P.**—I should be much obliged if you will be kind enough to let me know, through your paper, whether there is any formula for toning P.O.P., which helps to give brilliancy and contrast to prints from soft negatives; when the prints are required for reproduction this is an advantage, or is there on the market any P.O.P. specially prepared for answering the same purpose?—G. B.

One toning bath is very little better than another for this purpose. The best way to obtain greater brilliancy on ordinary P.O.P. is to print very faintly and develop with one of the acid developers or by the alkaline method of the Paget Company. The lighter the printing the greater the contrast obtained. A special P.O.P. for great contrast is the Rembrandt, for which Houghtons, Ltd., are the agents, we believe.

**RIGHT TO PHOTOGRAPH.**—Will you kindly reply to this query? We have a canal passing through this town, owned by a railway company. The towpath is open to the public. Can this railway company prevent me taking views from towpath and publishing them as pictorial postcards?—CONSTANT READER.

Certainly not—that is, if the towpath is a public thoroughfare. Even if it is not the most the railway company can do is to order you off as being a trespasser. If you secure the photographs you cannot be prevented from publishing them as postcards, or in any other form you may desire.

**PORTRAITS WITH NATURAL BACKGROUNDS.**—In your journal this week there is an article on "Portraits With Natural Backgrounds." Will you kindly let us know if the prints are painted over with ordinary moist water colour gamboge, and if so, we wish to know if the prints do not cockle in the centre by reason of the moisture?—LOWTHIAN BROS.

The gamboge usually employed is such as is sold by chemists, or by most good oil and colourmen. The prints do not cockle to any extent, and even if they did the paper would be pressed flat in the printing, and so cause no trouble. Only a thin coating of the gamboge is required.

**OUTDOOR OUTFIT.**—I am thinking of having a complete outfit, suitable for taking shop fronts, large buildings, school groups, and all classes of outdoor work. Will you kindly give me advice as to what kind of lens would be suitable and what size camera? I am open to pay a fair price for same.—MIDGET.

The best lens would be one of the anastigmat type, working at about  $f/6$ , if price is not an object. The next best would be one of the rapid rectilinear type, which has an aperture of  $f/8$ . As regards the size of camera, that, of course, must depend upon the size of the pictures you desire to produce. We should advise you to get price lists from the lens makers, and the manufacturers of apparatus, whose advertisements you will find in another part of the journal. From them you will see what will best suit your requirements—and pocket. We should advise you to get at least a whole-plate size, and we would suggest a camera possessing a close wide angle movement, and facilities for raising the front when the bellows is only moderately extended.

**A CAMERA WANTED.**—1. May I ask for information concerning the following, through the medium of your widely read journal? I want to know whether it is possible to obtain, and if so, where, a hand and stand folding camera, half-plate or postcard size,

which will take wide angle as well as long focus lenses, which will be perfectly steady when used on a stand for zontal, as well as vertical, views. What I mean is a camera something of the type of Butcher's "Minimum," or of Houghton's "Tudor" cameras, but, unlike these, so constructed as to the lenses already mentioned. In my experience all cameras of this class can only be used for vertical pictures, inasmuch as, when placed on a stand for horizontal ones, they vibrate the slightest movement of wind or shutter, and moreover, cannot be used for wide angle exposures. I may add that about to take a prolonged journey for photographic purposes and for special reasons it is necessary that the camera used be of the lightest and smallest. 2. May I further ask if any reader can tell me of any practical method of using flat half-plate in a double back (other than the various "packs" now on the market), so that they do not cockle up? So far I have not been able to use these films, much as I would otherwise like in consequence of their habit of refusing to lie flat, and the getting injured and out of focus.—VIATOR.

1. You had better get a folding camera of square build (reversing back), of which both the makers you name sell several patterns. You can obtain these with the necessary wide angle movement. 2. Any large dealer will supply both carriers and cut films for half-plate size. If no larger than this you can get them to lie flat. Naturally you will have some difficulty in carrying the thin pack films flat in dark slides.

**A COUNTRY-IN-TOWN Exhibition.**—Last year we called attention to an interesting project in the shape of a "country-in-town" exhibition, and it has now been definitely decided to open it at the Whitechapel Art Gallery, from July 5 to the 19th. Mr. Carrington is the president, and Mr. J. C. Medd chairman of the Executive Committee, while Canon Barnett, of Toynbee Hall, is the treasurer, and Mr. Wiltred Mark Webb (of the Selby Society) hon. secretary. The exhibition will consist of five sections. In the first will be living things, such as plants which have been or might be grown in London and in London schools, aquaria, vivaria, and bee-hives. Pictures and models from London and other urban centres will come into a second division and show the planting of streets and open spaces, children's gardens, playgrounds, town gardens, garden suburbs, and railway embankments. The third section will be given over to material appliances. The fourth will consist of plans specially drawn for the improvement of certain areas in London, while the last will deal with city life in Japan and other countries. As no charge will be made for admission to the exhibition, the committee would be very glad of contributions towards its cost. These should be sent to the treasurer, while all offers of help in the organisation of suggestions for exhibits should be made to the hon. secretary at the "Country-in-Town" Exhibition at Toynbee Hall, Whitechapel, E.

THE shop window of Mr. T. Wilson, photographer, New England, Peterborough, caught fire last week, but the flames were extinguished before much damage was done. How the fire originated is not known. The sun was shining very hotly on the window when the accident occurred.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received only to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

**Professional Colour Photography.**—To-day the St. James's Studio and Rotary Photographic Company is to be opened, exclusively for photography, in Old Bond Street. An article, illustrating the enterprise, records similar steps on the part of the Plymouth Photographers, Heath and Stoneman. (P. 366.)

**An international exhibition is proposed for Paris next year with co-operation of the "Chambres Syndicales."** (P. 361.)

**A photographer whose premises were flooded by the sea, involving damage of much furniture and apparatus, failed to recover damages from his landlord on the ground that the protecting sea wall had not been kept in repair.** (P. 367.)

**He show case, charges for sittings, a standard minimum rate for photographs, are among the topics discussed by the P.P.S. of N.Y.** (P. 368.)

**Precautions needed in home-sensitising carbon tissue are dealt with in connection with the adaptation of the sensitising to the negative.** (P. 363.)

**Diffraction grating spectroscopic cameras are discussed by Mr. E. J. Wall in the third article of a series dealing with the use of the spectroscope for photographers.** (P. 364.)

**Diffusion of definition in portraiture is warmly commended by an American writer.** (P. 370.)

**The syllabus of courses of instruction in photography has been published by the Victoria University, Manchester.** (P. 370.)

**Another film envelope has been patented; also a clockwork release and instantaneous shutter.** (P. 371.)

**The Photographic Survey of Surrey reports a year of progress. The classification of the photographs collected by the Survey is given on page 370.**

**Eighteen hints on retouching were given in a paper by Mr. H. Gordon Stollard before the North Middlesex Society.** (P. 374.)

**Humours of the dealer's counter occupied the L. and P. last week.** (P. 374.)

## EX CATHEDRA.

### The Royal Academy.

Since it has become fashionable amongst critics to lament, year by year, that the current exhibition at Burlington House reaches a lower level in the degradation of art than its predecessor, we shall perhaps be thought peculiar when we venture to say that we find the present show quite up to the average, and thoroughly representative of English art to-day. This does not mean that we find nothing there undeserving of its place; nor that we do not think a few of the older men might with advantage rest on their laurels rather than submit themselves to damning comparison with younger artists. Of course, there are many things that are an offence to people who can discriminate between the artistic and the vulgar; but even some of the worst of these are clever technically—a deplorable complication. Next week we shall publish some impressions on the exhibition as fully as space will allow; but in the meantime we cannot refrain from alluding to what is the crying shame of the collection. For absolute incompetency and vulgarity the two life-sized portraits of the King and Queen, painted for the Canadian Houses of Parliament, are not to be excelled. In this matter, however, the Royal Academy must not be blamed. This pair of specially displayed and draped exhibits are exceptional cases from which selecting committees must withhold their jurisdiction. King Henry the Eighth commissioned Holbein to make the royal portraits; King Charles the First commissioned Vandyke; King Edward the Seventh, if he did not actually commission, at least commands the exhibition of masterpieces by Colin Forbes!

\* \* \*

### Exhibitions in Paris.

By the same post which brings us an English prospectus of the Exhibition in course of organisation by M. Gastine, we receive a circular issued jointly by the "Chambres Syndicales," announcing an international exhibition of photography to be held in Paris next year under the patronage of the "Chambres," and with the co-operation of the Photo-Club and the Société Française de Photographie. An exhibition committee has been formed to prepare the scheme which is to take effect in the early part of 1907. Apparently the announcement of the proposed exhibition is made at this early date with the desire not only to allow the project to be known in all parts of the world, but also to increase the difficulties of those who are carrying out the arrangements for the exhibition, our references to which has led to the publication of several communications from M. Gastine. If the aim of the Syndicales is that the exhibition proposed for July next should be abandoned, we are afraid they will be disappointed, for the Government support which, we are assured, has been accorded to M. Gastine,

will be sufficient to provide the material for a large exhibition. The whole question is not one which keenly interests the British photographic public, although it will be curious to watch the lively warfare upon which our Gallic neighbours seem intent.

#### A Question for Tenants.

A case of importance to photographers in seaside resorts came before the Folkestone Court the week before last. A firm of photographers sued their landlord for £100 for destruction of property lost through the sea wall in front of premises occupied by the plaintiffs not having been kept in proper repair. The house in question was 25 feet away from the wall, but the latter breaking down under a heavy sea, the house was undermined, and the rear portion of the premises fell, taking with it much furniture and photographic equipment. The judge summed up for the defendant on the ground that the sea wall was not part of the demised premises, and a jury of builders assessed the damages of the plaintiffs, in view of an appeal, at £20. The case is one which shows the necessity of a carefully drawn up agreement when taking premises on or near a sea front.

#### Camera Shyness.

In a recent lecture before the L. and P., Mr. Malby, in referring to attempts to snapshot children in the slums of London and other large cities, said that it was almost impossible to obtain more than one shot per day in any one street, as the youngsters, immediately they discovered what one was about, were off like wild rabbits. This behaviour seems to us so utterly uncharacteristic of the British London child that we are impelled to think that Mr. Malby must have experimented in distinctly alien quarters. In a good many East-end slums British children are rarities, but where they abound we never noticed any particular shyness of the camera, excepting on the part of the girls, and even they are not usually shy enough to run away, only sufficiently so to put on the most idiotic expression they can command and stand as stiffly as possible. As for the boys, one boy speedily becomes many if a camera is on view, and with many boys about photography soon becomes impossible. Camera shyness is, however, very prevalent with foreign children, and even with their elders. We once strolled through a French market-place with a camera, innocently expecting that something in the way of a good subject would present itself. But the subjects worth faking were scarce, for the most prominent objects in view were umbrellas which were always turned in our direction. The great interest taken by the London street urchin in every unusual proceeding is often most embarrassing. One artistic acquaintance of ours hit on an excellent remedy for this inconvenience, which remedy took the form of a well-bred British bulldog of imposing aspect at the end of a long string attached to the artist's stool. The ground inside the circle commanded by the bulldog was then sacred ground that no stranger ever ventured upon, however great his curiosity.

#### Colour Photography in Horticulture.

One sign of the intensified interest which growers of flowers and fruit are evincing in the possibilities of colour photography was provided by the delivery of a lecture on the subject before a recent meeting of a horticultural society on the south coast. Colour photography is peculiarly the need of the florist and seed merchant, for the obvious reason that the exhibition of his products to customers at a distance is a matter of extreme difficulty on account of their perishable character and fragility. Hence those who are taking steps to embark on colour

processes in a business way will probably find firms such as these the easiest to do business with, and such work as they will have to give out is fortunately not the most difficult, and can usually be undertaken in a bright outdoor light.

#### Photographic Survey in Surrey.

The published report of the Photographic Survey and Record of Surrey shows the excellent lines along which the work of the survey photographers has been done, and might well be studied by other photographic bodies desirous of taking up this most commendable application of photography. The work of the survey is split up into six sections—architectural, art and literature, anthropological, geological, natural history, and passing events—each of these sections being under the direction of a committee capable of advising individual workers. Proof of the success which has followed this sub-division of activities is found in the fact that the number of entries in almost every section has increased over last year's, and the scheme, it would seem, secures the description of photograph which may be profitably preserved. As a guide to other societies, we reprint on another page the classification adopted by the Surrey people, commending it as applicable to almost any district.

#### Photographic Record Specialised.

Last year we referred to the work of E. S. Curtis, an American photographer who for some years past has entirely devoted himself to the portrayal of Indian life and character with the camera. This self-allotted labour will absorb his time for several years yet, but it is interesting to note that an exhibition of Mr. Curtis' photographs recently held in Washington has been visited by President Roosevelt, and has attracted the notice of Mr. Pierpont Morgan, by whom the sum of £15,000 has been guaranteed to see the work completed. Writing to us some time ago, Mr. Curtis informed us that in regard to reproduction of his work in the magazines he had stood out against current editorial notions of what should be paid for the right of reproduction. He had taken the stand that such work was worth as much as original productions of the best artists, and the magazines have used his work on these terms.

#### The Camera in Advertisement Designing.

The relative positions of the lithographic artist and photography have recently undergone reversal; the "handmaid of art" having become, in the showcard-producing industry, the lady superior. It cannot be denied that attempts to enlarge and colour complete photographs have been almost invariably dismal failures; but the modified methods now in vogue seem to give absolute satisfaction to the makers of soap, meat extracts, and other commodities. An idea of the "motif" having been settled upon, the next step is to photograph the figure required—child, winning damsel, or what not. This is done without any effort to complete the *mise en scène* by suitable background and accessories. All such work is left to the artist, who makes an enlarged drawing in colour, whilst obeying his instructions to preserve the exactness of expression of faces. Faults of pose, clumsiness of hands, largeness of mouths, and other photographic misfortunes, it is also his duty to amend. The result is a highly tickled-up piece of realism in gaudy colours, which does very well for tobacco and starch, though it would, perhaps, scarcely satisfy poster-users such as the North-Western Railway Company, whose latest posters are the high-water-mark of poster art, and for popularity run Millais' "Bubbles" very close. Cheapness is probably the chief recommendation of the new method.

## PRINTING PROCESSES.

## XXI.—CARBON.\*

the previous articles on this process it was assumed that the tissue used was purchased ready sensitised, and there are some positive advantages attending this. One of them is that it can be relied upon as being in good condition when received; another is that the trouble, little as it is, involved in the sensitising and drying, is saved. Still another is that tissue sensitised in the making—that is, by bichromate being added to the pigmented gelatine before the paper is coated—keeps much longer than that which is sensitised by its immersion in a solution of the salt. The tissue as supplied ready sensitised by the manufacturers, is adapted for negatives of what may be termed average type, and, therefore, is not so well suited for the use of a widely different character—say, exceedingly fine or abnormally hard—as tissue which is specially sensitised to suit them. The tissue that best suits the former class is one sensitised in a weak solution of the bichromate, and that most suited for the latter, in a strong one. Good prints can be obtained from quite feeble negatives of tissue weakly sensitised, and harmonious ones, from negatives that possess even very harsh contrasts by suiting the tissue to them in the sensitising. What may be described as a weak bath is one of about 2 per cent. strength, and a strong one from 5 to 7 per cent.

The stronger the bath used the more sensitive the tissue will be, and the shorter the time it will keep in good condition. Conversely, the weaker it is the less sensitive will be the tissue, and the longer time it will remain in good working order. It may be taken that, as a rule, the commercial ready sensitised tissue is about equal in sensitiveness and character to that sensitised in a bath of about 2 per cent. strength. It is not really necessary, in practice, to have baths of varying strengths to suit different classes of negatives, as the same end may, practically, be attained by using a solution of medium strength and varying the time of immersion in it, a short immersion being equivalent to using a weak bath, and a long one equal to employing a strong solution. Again, if the superfluous solution, with a short immersion, be removed with a squeegee it will be still more weakly sensitised. What, then, should be the strength of the solution most useful for all classes of negatives have to be dealt with? About 2 to 4 per cent. will be found a useful average, for which the good formula is as follows:—

Bichromate of potash	6 ozs.
Water	... 1 gallon.
Liquor ammonia	... 3 or 4 drams.

Hot, or even boiling, water may be used in making the solution, as the bichromate is then quickly dissolved, while in cold water it is slow of solution; but the ammonia must not be added until it is quite cold. The object of the ammonia is to neutralise any free chromic acid there may be in the bichromate, which, if left, would impair the solubility of the tissue, and its keeping qualities. An excess of the ammonia does not harm, as it flies off as the tissue dries. It is well to make up a good quantity of the solution at a time, as it can be used over and over again, until it becomes quite of a brown colour. The advantage of making a large quantity at a time is that it can be decanted from sediment when used, and thus filtration each time is avoided, even when the bath has many times been used. Some workers even prefer a moderately used bath to a quite new one.

For sensitising a good quantity of the solution is decanted into a dish—say to a depth of a couple of inches or more—and a piece of the tissue immersed, all air-bells, back and front, being removed with a flat camel-hair brush or the

finger. The sensitising may be done in ordinary daylight, as the tissue is quite insensitive while it is wet. If weakly sensitised tissue is required it should be removed in about a minute or so, and then squeegeed on to the plate; if a very weakly sensitised one is desired the squeegee should be heavily applied, so as to remove as much of the solution as possible. If a strongly sensitised tissue is required, the time of immersion may be extended to five or more minutes and the squeegee used with but slight pressure, only just sufficient to equalise the solution on the back. For medium sensitiveness three minutes will be a good time. If the tissue is not dried on a plate the best way is, as it is removed from the bath, to draw it face downwards over the edge of the dish, or a glass rod fixed to it, to remove the superfluous solution from the front, and then lay it, coated side upwards, on a blotting board, which will absorb that on the back, and then lay the board on a couple of lines stretched across the room.

It should be kept in mind that temperature is a factor in the sensitising. If it be low the solution is more slowly absorbed by the gelatine than when it is higher, and allowance should be made for this in timing the immersion. In very hot weather it may be found necessary to cool the solution by the addition of a little ice, for it is a somewhat curious fact that gelatine is more soluble in a solution of bichromate of potash than it is in plain water of a similar temperature. The temperature of the solution in hot weather should not exceed 55 or 60 degrees Fahr., lower is better, or there may be a danger, with some tissues, of the coating running when it is hung up to dry, or it might, on account of its softness, be pressed out by the squeegeeing. In hot weather some workers add methylated spirit to the sensitising bath, in the proportion of about an eighth or a tenth of its bulk. This restrains the solvent action of the bichromate, and at the same time facilitates the drying of the tissues.

It may be mentioned that it is not necessary that the dish be as large as the tissue to be sensitised, provided its longest dimension is a trifle more than the width of the tissue. In this case the tissue is rolled up, immersed in the solution, and then slowly unrolled and re-rolled over and over again, of course keeping it well under the solution for the requisite time. If, in the sensitising, the fingers or nails become stained with the bichromate, they should at once be rinsed in dilute ammonia, and afterwards washed with warm water and soap. This will remove all traces of stain.

A word or two on the drying of the tissue may be said here. The drying, when the gelatinous surface is exposed to the air, must be done in a darkened room where the atmosphere is free from noxious fumes, such as those from burning gas and the like, and the drying should be completed in about six or seven hours, particularly if the temperature is high. If this time be much exceeded, especially if injurious vapours be present, the tissue may prove to be more or less insoluble, and will not keep for long. Also, if the tissue does not turn out actually insoluble, its surface may be what is termed "tinted," that is, slightly fogged. A better way of drying when small sizes—say up to 18 x 15 or so—are required to be dealt with, is, after the tissue is removed from the bath, to squeegee it on to a ferrotype plate, or a sheet of tin or zinc, and allow it to dry on that. Then the drying may be done in any ordinary room, as the coating is protected from light by the yellowness of the paper backing, and also from any injurious fumes there may be in the atmosphere. The drying, it is true, then takes somewhat longer than when both sides are exposed to the air, but that is not of much moment, seeing that the actual surface which is to bear the image is so well protected from atmospheric influences.

\* Concluded from page 264.

## THE USE OF THE SPECTROSCOPE.

### III.

WE now come to the consideration of the diffraction grating, which may be defined as a series of parallel lines ruled either on glass or metal. These are extremely expensive, and the finest are those ruled by Rowlands on metal with 10,000, 14,438, or 20,000 lines to the inch. Of late years Rowlands has ruled them on concave metal speculums, which do away entirely with the necessity of using a lens to form an image, for, of course, they act exactly like an ordinary concave mirror, and form a real image. The great disadvantage of these concave gratings, for such simple work as the average photographer is likely to engage in, is that the sensitive surface must be bent to a curve, which totally excludes the testing of plates.

The disadvantages of the plane metallic grating are that the image lies on either side of the slit and the mounting is cumbersome, extreme delicacy of adjustment is required, and, moreover, the grating is costly—far more so than any work that we are treating of deserves.

#### Diffraction Grating Replicas.

Mr. Thorp, of Manchester, has, however, been able to take casts of a Rowland plane grating in celluloid, and these are quite satisfactory in performance and reasonable in price—namely, fifteen shillings. It is these, then, that we need only consider.

The method of making these replicas was described at length in the *BRITISH JOURNAL OF PHOTOGRAPHY* for November 29 and December 29, 1905. There is not the slightest difficulty in following the directions given, and excellent results are obtainable, even when one does not go to the trouble of purifying the pyroxyline, for I have obtained very satisfactory results with a sample of commercial celluloid varnish, which had been standing undisturbed for three months, so that all the impurities had settled to the bottom of the bottle. The only thing to fear is dust settling on the wet film.

These replicas are, of course, used by transmitted light, the slit being placed opposite to the centre of the grating, and with its jaws parallel to the ruling. When one of these is examined, and the eye is placed in a straight line with the light, practically no spectrum can be seen—merely the white slit; but if the eye be moved to one or both sides the spectrum will at once be seen. This is roughly shown in the following diagram, Fig. 1, in which S is the white central image of the slit  $V^1R^1$ , the first order spectra on each side, separated by dark intervals from the central image;  $V^2R^2$  are the second order spectra, and  $V^3R^3$  the third order spectra. It will be seen that the

Fig. 1.

third order spectra overlap the second, and the second ultra-violet spectra overlap the red end of the first. It is important to note this, for it may give rise to photographic action in this region, and be quite misleading. A simple dodge will get over this, as will be seen later.

To anyone who has one of these transmission gratings my advice is to rig it up temporarily and project the spectra on a white card, and note whether one first-order spectrum is brighter than the other, because this may easily happen, and is due to a

peculiarity in the ruling of the original grating. It was stated by Mr. Thorpe some time ago that he hoped to make replicas in which nearly the whole of the light was thrown into one spectrum, which would be a gain from some points of view.

For our work the first-order spectrum is quite sufficient, though the spectrum in the other orders is much longer, but the overlapping is so great and the illumination so poor that we can ignore them altogether, except so far as they may give rise to scattered light in the camera.

It will be obvious from Fig. 1 that if our plate is placed opposite to the slit we shall have a white image, and may or may not obtain a spectrum on the plate, so that our camera must be specially arranged with the slit right at one side, or the top, and the plate at the bottom. This plan has been adopted by Thorne Baker, as shown in Fig. 2, in which S is the slit,  $L_1$  is the collimator lens, G the transmission grating,  $L_2$  the

Diffraction Grating.

Fig. 2.

camera lens, and PQ the position of the plate. The external measurements of this are 24 by 12 by 3 inches. This is an uncouth-looking instrument, and far too bulky for ordinary work.

#### Tallent's Spectroscopic Camera.

Tallent's diffraction camera is much handier and equally efficient for all plate and screen testing. This is shown in Fig. 3, in which D is the slit, E the collimator lens, F the diffraction grating, and C the camera lens, RCV being the dark slide which slides in grooves past a narrow aperture, which enable one to obtain five spectra on a quarter-plate.

It will be noted that the diffraction grating is mounted on a 60 deg. prism, and the purpose of this is to refract the central white line to the bottom of the camera, whence it is prevented from reaching the plate by the thick dotted screen, and to bring the first-order spectrum in a line with the slit. The whole arrangement is extremely compact, handy, and reasonable in price. The slit is adjustable, and a numbered scale can be fitted close in front of the plate, so that it is easy to identify any particular region when it has once been scaled.

#### The Ives Camera.

Mr. Ives has also made a diffraction grating camera with replicas, in which the latter is cemented between two 70 prisms, which necessitates setting the grating obliquely to the body of

camera. The slit in this camera is placed near one of the ends of the camera, as the direct vision line, instead of being in the middle of the spectrum, is in the ultra-violet. A novel feature is the naphthol yellow screen placed in front of the slit. The spectrum from A to E, thus cutting out the overlapping ultra-violet of the second order.

of action or sensitiveness of the plate to the particular regions of the spectrum or colours, it will be obvious that the prismatic spectrograms will show much greater colour sensitiveness than the diffraction.

It is, of course, possible to translate, as it were, the prismatic action into the diffraction by comparing the density for a given

The Tallent Diffraction Spectrographic Camera.

Fig. 3.

### Properties of the Diffraction Spectrum.

It will be as well to point out here the advantages of the diffraction over prismatic spectrum. In the latter the distribution of the colours or the position of the lines is dependent on the number and the refracting angles of the prisms, and the kind of glass of which they are made, whereas, with the diffraction grating, the distribution is practically always the same. Put it a little more practically, the red end is crowded together and the blue and violet end spread out with prisms, whilst with a diffraction grating the distribution is more even. This is well illustrated in Fig. 4, which is taken from Hubl's book,

Fig. 4.

"Three-colour Photography," and is used by him to show how misleading the prismatic spectrum may be, for if we represent the photographic action of the spectrum on a plate by the usual curves, and the height of the curve as representing the amount

region, say, for instance, from C to D, and calling this  $a$  and the density  $m$ ; then, in the diffraction spectrum this region will occupy a greater space, and, calling this  $b$ , the density  $n$  must be less, for the action is spread over a greater surface, then  $am = bn$ , or  $n = \frac{a}{b} m$ . Such comparisons as this are, however, not likely to be called for.

All the remarks as to the slit width, etc., made in connection with the prismatic spectrum apply equally well to the diffraction grating camera, so that we can proceed at once to determine the actual positions of the Fraunhofer lines, and therefore of the colours.

### Mapping the Spectrum.

I am assuming that the actual position of these lines is not known; if they are, and can be recognised visually, then all that is required is to examine the spectrum with a scale, note the number of the scale agreeing with the various lines; but, assuming that one knows generally where the lines are, but not their actual position, it is extremely easy to map them out, using nothing more than a bunsen burner and a few salts, such as lithium, sodium, thallium, strontium, and potassium chlorides. Magnesium ribbon will also be required. Small quantities only of these salts are required, for if the scale is once made it can always be used. The greater the number of salts used the more correct the scale, but with a bunsen burner, common salt, magnesium ribbon, and potassium chloride we can map in really all we want, for the potassium will give us red and blue lines, sodium the orange, magnesium little  $b$ , or the green, and the lower part of the bunsen flame the well-known Swan spectrum.

With the aid of an induction-coil and a vacuum tube filled with hydrogen one can easily map in the red line C, F in the green-blue, G in the blue, and little  $h$  in the blue-violet. The cost of a hydrogen tube is not much; but if one has not an induction-coil, and has to borrow the use of one, it would be

far better to obtain one of the compound vacuum tubes suggested by Professor Collie containing hydrogen, helium, and mercury, which gives fifteen lines almost equally distributed between  $\lambda 706$  and  $\lambda 434$  and which render anything else quite unnecessary.

Mr. A. T. Newton, in "Penrose's Annual, 1906," p. 81, gives an excellent method for scaling the spectrum when one has an arc light at command. It is frequently recommended to use the iron arc, or for fine work the spark spectra of cadmium, copper, or an alloy of, cadmium zinc, and lead, but the trouble with all these is that the number of lines is so great that confusion is the result.

Again, it is often advised to use, not the wave lengths, but the oscillation frequencies—that is, the number of waves in one centimeter in vacuo, for scaling purposes, because the curve then becomes nearer a straight line, or we are advised to use the squares of the oscillation frequencies when it becomes nearer still to a straight line. These are refinements, and unless one has a table of oscillation frequencies for every wave length,

and maps this as well, there is trouble in reading off the results. It is far easier to use an empirical scale and memorise the scale numbers of the lines.

This is possibly a convenient place to support the statement previously made, that for all ordinary purposes the expression wave length 589 or  $\lambda 589$  is sufficient. Supposing we start scaling a spectrograph, and wish to be accurate, and assume that the length of our spectrum to be four inches, taking the two lines E and little b, which have wave lengths of 527 and 527.5 respectively, the separation is by actual measurement a quarter of an inch. Now, it must be a fairly closely ruled scale which will show ten divisions in a quarter of an inch; besides, if one did have such a scale, it is doubtful whether it would be of any practical value for such difference in the sensitising power of a dye, or the absorption of a filter would be negligible. Now is the expression 5270 more accurate, because such a line may be one of the three standard wave lengths, 5270.448, 5270.495, or 5270.533, and thus be due to calcium or iron.

E. J. WALL, F.R.P.S.

## PROFESSIONAL COLOUR PHOTOGRAPHY.

THE present issue of the BRITISH JOURNAL OF PHOTOGRAPHY may properly be regarded as marking an important step in professional photography, inasmuch as it records the opening of the studio of the Rotary Photographic Company for portraiture in natural colours and the additional fact that this modern development of the business of the professional portraitist has been appreciated as swiftly in the West of England as in the heart of the West End of London.

Indeed, a firm of Plymouth photographers, Messrs. Heath and Stone-man, can claim to have anticipated events in London by opening their studio for colour photography some week or two ago, whereas the opening of the Rotary Studio, after several postponements, is not to take place until to-day.

The Rotary Company's studio is situated in a new block at the corner of Old Bond Street and Piccadilly, the two topmost floors

The Studio in the Rotary Co.'s new Bond Street Establishment for Colour Photography.

Ante Room and Approach to Roof Garden, St. James's Studio.

which are occupied by its suites of reception and dressing-rooms studio. The St. James's Studio, as it is called, is to be devoted exclusively to colour photography, not of portraiture only, but of works of art, objects of natural or artificial origin as may be desired reproduced in colours. The process is a three-colour method in regard to which no extravagant claims are made. The negatives are made in a repeating back as shown in the photograph of the camera. The combination of plates and filters is of a kind which permits of exposures being cut down to as little as ten seconds for all three negatives, and in announcing their success in this direction we believe the Rotary Company do not claim the possession of exclusive facilities. On the contrary, they desire it to be understood that photographers who will go to the trouble and expense may adopt a practice similar to that of the Studio. In the matter of preparing the prints from the three negatives the process

employed by the Company is that involving their well-known "carbon stripping films," the use of which in professional portraiture was the subject of an article in our own pages some months ago. The results by the same process formed a notable series of exhibits in the collection of examples of colour photography which we brought together at these offices. Since then, we have no doubt, finer specimens have been obtained, and these we shall be able to allude to next week, our present notes being made prior to the actual opening of the studio, from information accompanying the ticket of invitation.

Of Messrs. Heath and Stoneman's enterprise, we can say that it is not a spasmodic effort to compete in a direction which is attracting attention at the moment. The firm has been experimenting in colour work for a year or two past, and the present process, which they are applying commercially, is an adaptation of three-colour methods to certain details of their own origination. Presumably Messrs. Heath and Stoneman prepare their three-colour prints by the carbon process, since their firm has long executed a very large proportion of its output in that printing process. At any rate, the innovation has been sufficient to stir local journalistic circles into

The Camera and Repeating Back in the St. James's Studio.

Reception Room of Heath and Stoneman's.

writing in warm though not foolish appreciation of the "Photographic Colour Portraits" of the Plymouth firm. The "Western Daily Mercury" refers in a recent issue to the accomplishment of Messrs. Heath and Stoneman as successful in the extreme, and comments on the excellent three-colour portraiture. According to the article the minimum exposure of which the process permits is half a minute, but that, we should suppose, may be still further reduced with improvements in panchromatic sensitisers.

Photographers as a whole will await with interest the verdict of leaders of the craft as to the commercial possibilities of three-colour

portraiture. It will not be supposed that portrait colour photography can be made to pay in all and every district. Even posing that the results are immeasurably superior to those produced by hand colouring, it must be some time before a public be awake to that superiority, and perhaps such a public, even more keenly awake to the superiority in the price. Indeed, entrance of three-colour into commercial photography is so utterly new that it is rash to prophesy anything of it. It will be some time before sufficient evidence will be forthcoming to permit its facilities being judged.

## AMERICAN PHOTOGRAPHERS IN CONFERENCE.

WE publish below the continuation of the report of the Convention recently held in New York by the Professional Photographers' Society of New York, at which a number of questions bearing solely on the business side of photography were put forward and discussed. The views of members of the P.P.S. on free sittings and school rates were contained in our last issue. We now give the report of the Convention, according to the "Photographer," on price cutting, charges for sittings, minimum rate, and the show case.

### PRICE CUTTING.

"Is there ever a time in the photographic business when it pays to cut prices?"

Various Members: No, no. Cut it out.

A Member: Why do they do it?

Mrs. Beals: I will tell you why I did it. This last Fall, business was dead, and I had to do something to get business in. Prices in my locality were higher than people could pay. Recently I have taken to cutting prices, and people come in, and when they come in I charge them more.

A Member: In other words, her effort was only a bluff. (Laughter).

Mrs. Beals: I sell them at prices they want, if they want that kind of work; when they get in there I show them better work, and they always take the more expensive work.

A Member: Mr. President, I think that the idea of cutting prices is something that should never be done in any case, because it belittles you in the eyes of the community. Your pictures are not worth what you ask for them, or you would not cut the price; I think under no circumstances should it ever be done.

Another Member: Mr. Speaker, what do you do in the case of schools? Everybody cuts the prices on that.

A Member: I never did. I will say, however, for your better information, that we have no big schools in our locality.

Mr. Bradley: That solves that question.

A Member: That is all right, cutting your prices, but now I want to tell you just a little thing that happened in our town. Supposing you were in business for five years, charging 15 dols. to 25 dols. a dozen for pictures. A new man comes in and he puts up photographs for a dollar a dozen. A person wants to get a picture taken, maybe to send to his mother, or sister, or some relative, and he says, "Where will I go? Well, I will go to Brown." He walks along and he sees a sign out. He heard that Brown makes very good pictures, and he has a friend of his who was very well pleased. He walks down and sees a sign, a dollar a dozen, and he says, "Well, I think that dollar-a-dozen picture will do me now, and I am going to have better ones made later on." Who is making the money? The public is making the money, and we are out.

Mr. Phillips: Just in answer to the person who has spoken, I would like to give a little personal experience. I don't want to tell my past life—

A Member: You'd better not. (Laughter).

Mr. Phillips: —but there was a little experience which happened in our town. I might liken myself to the man who had been in the town for ten years and had an exclusive business, and a new man came in and cut prices. This is what happened: We were making photographs for a certain sum, and a new man came to town and put in a studio next door in such a way that a great many people went into that entrance when they were looking for ours. That man reduced his price to one-half, for the cabinet photograph, of what we were getting at that time. Two months after he went in we raised our cabinet price just one dollar. That year saw an increase

in our business of 25 per cent. Now there is a case of actual fight and I say that the man who will make honest work—that is, he to himself—keep up his prices so that he gets compensation for his work, will be the man that will stand up in the long run, and will hear of him until he has gotten so old that he has ceased to be of use in active business. As to the man who cuts the price in photography in our town, the history of that has been that that man last just so long, and that period is a very short one. Most of the men who have been prominent in cutting prices have gradually wiped out, and we do not hear any more of them; but the firm can lay my hand on three of them—who have always stood at a higher price and a better picture, have gradually increased their prices as photography has improved and people have appreciated the firms who are in business to-day, are living well, and have a good bank account.

A Member: There is something to be said on both sides of the case. Speaking of my own personal experience, I never cut prices but once, and I leave it to the Convention whether I was justified in that case or not. I bought a business from a man at a satisfactory figure on his written agreement not to enter into business again. After completing the bargain he placed his property all in his wife's name and opened a studio two doors from mine and cut prices. As soon as he started and established his cut price, I cut immediately two dollars below him, and in the course of a week he reduced his prices to mine. That was in the summer time, and when the prices were reduced to the figure that we had reached them, business was done at a loss. I closed my gallery and took a vacation. When I came back the other man was *non est*. I was informed that he had borrowed money to leave town. I think that time I was justified in cutting prices.

A Member: As far as price cutting is concerned, yes, there are times when a person should cut prices. I went to Schenectady six years ago—this is about three and one-half years ago, and I started up a little business, but in the spring my lease expired and I had to get out. In the Fall I opened up another place. Some time ago I got sick and I was in bed four months, and my little place went to ruin, and my friends took away my camera and the little furniture I had there, and the rooms were vacant. When I came back from the hospital the landlord said, "Never mind about the money; I will pay me when you get it." I went there and I started in business. I was there two or three months and I didn't do a cent's worth of work. I made all my prices 3 dols. a dozen. Things went entirely wrong with me. I put them down to 2 dols. a dozen, and downstairs I had a sign, "Two dollars a dozen for fifteen days only," and I started to give a little brooch free, but the people would not come. I kept on there. Before long I started to do a good business there, and stayed there two years, and I made over 1,500 dollars last year.

ve one of the nicest studios in Schenectady, and I have now raised y prices. People, if they want to cut their prices, can cut them ording to circumstances.

Mr. Gaboriault: Some members have each given a little outline their lives in business. I would like to state that I have never ne any cutting. I bought a studio in Albany some five or six ars ago, and at that time they were doing a lot of this penny ante ssiness, and somebody told me, "You never can make a success of at studio; it has been a studio for thirty years, and everybody o ever went in there went out broke." Well, after I was there a le while I put out a one-dollar picture and introduced myself to the y. After six months running this one dollar picture I put out a o-dollar picture, and I ran that in connection with the one-dollar ture. At the end of the year I put out a three-dollar picture, d I ran that for a year with success. Six months later I put out our-dollar picture, with a greater success than any of them, and months later I put out a five-dollar picture, and that went; and

to-day I make more five-dollar pictures than I ever made of the one-dollar pictures, showing that you can increase your business according to your work. But if you are putting out a dollar picture, do it—do not give a three-dollar picture for one dollar. If you are putting out a five-dollar picture for one dollar, it is not fair competition.

Mr. Ray: I have tried both plans. If I were an established man in a town I would not cut prices, no matter what a newcomer did. I have found that out. But for a new man starting out, as I am, I find that it pays me to draw people in. A new man has to get attention some way. When he gets to cutting prices he does not have to cut down to one dollar a dozen. I make my limit of cutting down six dollars a dozen; fifteen dollars is what I would regularly get. At present I am getting in a great many people who would not come in at all if I asked them fifteen dollars. So it narrows down to the fact that a man who has an established trade should keep up his prices, and the new man should make his prices as low as he can.

### A STANDARD MINIMUM RATE FOR PORTRAITS.

"Is There Any Reason Why a Uniform Minimum Rate of 5 dols. a Dozen Should Not be Established by the Legitimate Portrait Photographers of the County?"

Mr. Lewis: First, I should like to ask what constitutes a "legitimate portrait photographer?" I know many men who are located in communities where five dollars a dozen is considered a good maximum price, and where a Garo or a Histed could get no more. These premises at once preclude the possibility of argument. Some of these men make photographs as low as two dollars per dozen, yet conduct their business in a straightforward, businesslike way, making portraits almost exclusively, and do not resort to schemes of any sort, a sober, honest, upright men, who do not want to be classed as other than "legitimate portrait photographers." Many of these men are doing as much for the upbuilding of the profession in their sphere as the men in the large cities who command ten times the price for their work. Therefore in answer to the question, I say, yes; there is reason why a uniform minimum rate of five dollars per

dozen should not be established by the legitimate portrait photographers of the country, or, rather, I consider it unfair to establish a rule barring from the ranks of the legitimate portrait photographers any one who makes photographs for less than five dollars per dozen, not considering his reasons, while possibly admitting another's who are turning out pictures which could be made at a profit for three dollars per dozen, but which they are telling the people are worth ten dollars per dozen, but by buying the ticket they can procure for five dollars and fifty cents per dozen. I am glad this question has been asked; I am glad to have the opportunity to express my humble opinion on the subject; and I sincerely hope we may have thoroughly defined the meaning of the term, "Legitimate Portrait Photographer." I am particularly concerned, and I believe there are others who would like to know, what is a legitimate portrait photographer, and what is illegitimate in the business?

### CHARGING FOR SITTINGS.

"Should a Fixed Charge be Made to Cover the Cost of the Sitting Where No Order is Placed? What is the Best Procedure in Such Cases?"

Mr. Lewis: I overcome that difficulty by having a price for the sitting and nothing else, at the outset. I make everything so much for the sitting and so much to print, and when people come in and ask how much pictures are by the dozen, I tell them I don't make pictures by the dozen; and if this puzzles them, I say, "We charge for the sitting. We charge three dollars for the sitting, and you select such prints as you want, and they are one dollar apiece." Unlike Mr. Hollinger's method, this is doing business on a business basis.

A Member: I always give my customers to understand that they are to pay for negatives whether they have any photographs finished or not. The price of the negatives depends somewhat on the grade

of the pictures, but I always give them to understand that there is a fixed price for the negatives anywhere from fifty cents to two dollars, and unless they are persons with whom we have accounts, we expect them to pay for negatives at the time of the sitting.

A Member: I think that the negative absolutely belongs to the sitter. You cannot take and publish or print any photographs if there is any objection to it. As for a deposit on photographs, I think it would be well at all times to get at least a dollar deposit.

The following questions attracted no discussion:—

"What Ratio in Price Should the One-Half Dozen Bear to the Dozen Photographs?"

"What is the Best Basis on which to Estimate the Cost of Production?"

### THE SHOW CASE.

"How Can the Show Case Be Made a Stronger Business Puller?"

A Member: Cleanliness and good work.

A Member: I would suggest the best thing to do for the next year to put in a certificate of the State Photographers' Association.

Mr. Shiro: Following out the suggestions that have already been made, I thoroughly appreciate myself the necessity of frequent change, and I have also found it very successful to put out a show case concerning somewhat to the season of the year. For instance, I put out case for Easter decorated with Easter lilies, and on the 4th of July decorate the case with the American flag. At Christmas time I put out what I considered a very tasty case, decorated with holly and evergreens, with a wreath in the centre and a large head back in the rear. I know that I have had orders on account of the cases.

Mr. MacDonald: I don't know that it would be of any particular interest to the majority of you to have the opinion of a New York man on this subject, but I have had a most curious experience as compared with the majority of people, as you know, in regard to show

cases. There are many of you who are living in comparatively small towns, but in those comparatively small towns they are putting up very much larger and more important buildings to-day than was the custom within, say, ten or fifteen years ago, and there is no doubt in my mind but that this proposition is going to be brought before some of you at some time or other. You are going to find that you are going to be able to get a studio in an up-to-date elevator building with a fine entrance and everything just about as you want it, but the building is going to be of sufficient importance so that the owners are going to object to your having a show at the door. That is a proposition that is going to come up among some of you some day or other; and I want to tell you that I would rather for myself be in an old-fashioned building with a good show case than the best building in New York without any, when it comes to ease in advertising. I am in a building, as many of you know, away down near the end of Broadway. My name is on a tablet with some four hun-

dred other tenants, and it is obvious that it is impossible for me to get a show case at the door. Were I able to get a show case which would be capable of showing only my regular size pictures, which are made on a 7 x 10 plate, I would be very glad to have them raise my rent a thousand dollars a year. Now that sounds like a lot of money; but I am in business for many years, and I want you to know that I could make more money out of that 1,000 dollars expenditure in the way of advertising than in any other line of advertising that is possible. I believe myself in pictures at the door; and do not let anybody flim flam you into the idea that you are so big and so strong that the absence of a case at your door is going to do you no harm. Take my word for it, it has cost me a barrel of money to prove it, and I know what I am talking about.

A Member: I think that perhaps I can give a novel way of showing pictures at the case. I knew a photographer in Leavenworth, a very successful man, and this was the method he adopted: Every week he put new pictures down in his case, with the names of some people who he knew would not object, saying that these people sat at his studio last week or some days ago. People would stop to see what the names were, and there was a continual stream of ladies in front of his studio.

A Member: With my class of trade, if I were to adopt that system, I should expect to go to my friends here and ask them if they would kindly donate me enough for my supper to-night. That is the difference of experience.

Mr. Lewis: I might say on the show case proposition that I have a store window. My place is on the ground floor, and I have been careless, as many men are, about attending to the window. Half the time there is nothing in it until someone comes along and asks me to put some more pictures in it; but I find that something after the idea suggested here of letting people find something and have some idea of what they expect to find, increases interest.

### PHOTOGRAPHIC SURVEY OF SURREY.

THE following is the scheme of classification adopted by the Photographic Survey and Record of Surrey to whose annual report we allude under "Ex Cathedra."

#### ARCHITECTURAL SECTION.

All buildings and structures of interest, whether ancient or modern. Churches, including monuments, furniture, stained glass, mural paintings, and bells. Ruins.

#### ART AND LITERATURE.

Art.—Paintings, drawings, and engravings. Sculpture and carvings (not architectural). Art work in metals. Pottery and glass. Tapestry, lace, and other fabrics. Art furniture and other objects of art. Direct photographs of persons.

Literature.—Printed books, when old, curious, or rare. Manuscripts. Maps and plans.

The Committee will be glad to receive information of the existence of objects of interest falling within their province, since a great deal that is most valuable is in private hands, and may otherwise remain unknown to them.

#### ANTHROPOLOGICAL.

Antiquities.—Prehistoric and historic (non-architectural).

#### PHYSICAL ANTHROPOLOGY.

Folk Lore.—1. Material objects. 2. Ceremonial. 3. Traditions (games, holy wells, social and religious subjects).

#### GEOLOGICAL.

Land contours, river courses, sections, fossils, rocks. It is advisable that a geologist be present when a geological photograph is taken.

#### NATURAL HISTORY.

Zoology.—1. Mammals—(a) Rare species; (b) habits; (c) homes and young. 2. Birds—(a) Rare species; (b) habits; (c) homes and young; (d) migration. 3. Reptiles. 4. Fishes. 5. Insects (including economical entomology). 6. Pond life.

Botany.—1. Trees, peculiarities of growth. 2. Shrubs and herbaceous plants—(a) Habitat; (b) peculiarities of flowering; (c) galls and other forms of parasitism.

Meteorology.—Halos. Remarkable cloud appearances. Hailstorms and frost effects. Lightning. Auroræ.

Photo-Micrography.—Astronomy.—Eclipses. Comets. Meteors, etc., etc.

#### TOPOGRAPHY AND PASSING EVENTS.

Topography.—Landscapes. Views of places of special beauty and interest. General views of towns and streets.

Passing Events.—Scenes of every-day life. Processions, carnivals, bonfires, etc.

#### ACCESS TO COLLECTION.

The collection is housed at the Public Library, Town Hall, Crodon, under regulations making it accessible to the public. It is hoped that, later on, local collections will be similarly deposited in other centres.

### DIFFUSION IN MODERN PORTRAITURE.

SHARPNESS is merely a matter of degree. The question is, what is the degree of sharpness required? That depends upon the purpose for which it is intended.

We are drifting away (writes L. Laurence in the "Photo-Era" Boston) from the "all-over sharp" idea. Great sharpness makes the portrait look as if you had a map of the skin and as though you could put a needle in each pore.

The eyes should always be sharp, but the face as a whole should be soft.

Images are made up of little discs, properly speaking, but when the discs are less than 100th of an inch in diameter we do not see the image as a disc but as a point.

One of the most important questions is, what do you consider enough softness, or what do you consider enough sharpness? If you are catering to people who want a fine, clean, sharp picture, you cannot refuse their desire, but you may take the benefit of the doubt and apply diffusion as much as you dare without harming their belief that you have given them a portrait that is sharp. It will only be a matter of time when they will appreciate your judgment.

Where you have detail clearly and sharply defined you have a clean, distinct border line which you cannot do away with unless you paint the face with lead. If you have a certain amount of softness say just a little softening of the outline, you will have done much to retain the character of the face.

By the judicious use of diffusion you can save one-half of the retouching, and you will come closer to a perfect likeness the less retouching you do. This does not, however, deprive the retoucher of a job, but their work will be facilitated and they will be able to turn out better work in a shorter time.

### PHOTOGRAPHIC INSTRUCTION IN MANCHESTER.

THE recently issued "Ordinances and Regulations" for degrees and certificate courses in the Faculty of Technology, Victoria University defines the preliminary courses to be taken by students for the B.Sc. (Vict.), and for a "certificate in technology," to be granted after a course of study of at least two years' duration. For the B.Sc. degree in applied chemistry, photography is one of seven optional subjects; the course of study, including, in addition to pure chemistry, physics (with laboratory practice), machine drawing, and paper manufacture. The syllabus for photography is:—

(a) The chemical and physical principles underlying the technology of processes in pure and photo-mechanical photography. The photography of colour. Sensitiveness and gradation of photographic surfaces. The principles involved in the construction of apparatus for photography.

(b) Technical processes used for the preparation of the more important photographic materials.

(c) Practical exercises in the analysis, examination and valuation of material used in photography. The qualitative and quantitative estimation of the constants of sensitive surfaces. The measurement of the constants and aberrations of photographic objectives.

For the "certificate in technology" the two years' course in photographic technology is as follows:—

First Year's Course:—French or German, Chemistry and Physics

tures and Laboratory; Principles of Pure Photography, Lectures; Principles of Photo-Mechanical Photography, Lectures; Practice of Pure Photography. Laboratory work.

Second Year's Course:—French or German; Chemistry Lectures and Laboratory; Principles of Pure Photography, Lectures; Practice of Pure Photography; or Practice of Photo-Mechanical Photography, Laboratory work.

Candidates before entering upon a course leading to a certificate are required to pass an entrance examination in the following subjects:—

English. (Composition with some simple questions in English literature).

Mathematics. (Subjects of the first three books of Euclid and algebra up to and including quadratic equations).

One other language. (Elementary).

Elementary science, including physics, chemistry and mechanics.

Candidates who have passed the Matriculation examination of the Joint Matriculation Board are exempt from the above.

In lieu of this special examination candidates may offer a certificate having passed any public examination of adequate standard as exempting from the whole or any part of the above entrance examination.

## Photo-Mechanical Notes.

### "The Globe" on Newspaper Half-tones.

The portrait of Dinizulu, published in a daily paper, may be an excellent likeness, but personally we should consider it lacking in detail. It consists simply of a black, oval smudge. We should advise our contemporary to save up the block. They can use it for King Menelik, if necessary, or a realistic picture of a London fog.

### The Emulsification of Asphalt.

A German patent, 170,133, June 3, 1904, has been granted to Dr. K. Mann, of Zurich, for a process of emulsifying asphalt and other substances insoluble in water. Soap and starch are dissolved in water by the aid of heat, which must be sufficient to dissolve the starch completely. To the warm mixture, asphalt, dissolved in benzole or other solvent, is added with constant stirring. The benzole vaporates and can be collected and condensed, whilst the asphalt remains finely distributed throughout the mass, and remains suspended if the mixture is stirred till cold, when it presents the appearance of an ointment, which is miscible with water. The materials necessary for making the soap, such as the fatty acids, fats, resin, etc., may be previously melted or dissolved with the asphalt. In this case the necessary quantity of alkali is incorporated with the starch paste, and the soap is gradually formed as the asphalt mixture is added.

### Zander's Four-colour Process.

In the current number of "Photographische Korrespondenz," it is pointed out that the principle involved in the Zander process is by no means new, for in an address before one of the scientific societies of Vienna on January 22, 1896, Dr. Eder said, "According to Hering there are four fundamental colours, red, green, yellow and blue. Working according to this theory all the manipulations necessary for three-colour printing may be adapted without difficulty to a four-colour system, and a four-colour print would be the result, in the production of which there is nothing actually to be overcome, and which ought to give very satisfactory results."

### PHOTO-MECHANICAL PATENTS.

Among the applications for patents made between April 23 to 28 is No. 9,726, by Donald Cameron-Swan, for improvements in the production of photo-engraved half-tone blocks.

A CAMERA Club in Bedford.—A camera club has recently been formed in Bedford and between forty and fifty members enrolled. The hon. secretary is Mr. W. H. Hodges, of 53, Beaconsfield Street, who will be pleased to hear from anyone interested.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between April 23 and 28:—

**LIGHT-TIGHT CASES.**—No. 9,448. Improved light-tight case for use in drying coatings on photographic plates or films. Thomas Frederic Crossley, 65, Chancery Lane, London.

**PROJECTION APPARATUS.**—No. 9,533. Improvements in projection apparatus. Martin Ball, 7, Southampton Buildings, London.

**REFLECTED IMAGES.**—No. 9,576. Apparatus for exhibiting reflected images. Frederick Muller, 65, Chancery Lane, London.

**APPARATUS.**—Improvements relating to photographic apparatus. Herbert Oscar Seaman and John Edward Rickards, 23, Strensham Road, Balsall Heath, Birmingham.

**PRINTING PROCESS.**—No. 9,796. An improved printing process. J. E. Bousfield, 4, South Street, Finsbury, London, for Ernesto Bianchi, Italy.

**FOCAL-PLANE SHUTTERS.**—No. 9,849. Improvements in focal-plane and other roller-blind shutters. Arthur Lewis Adams, 26, Charing Cross Road, London.

**APPARATUS.**—No. 9,987. Improvements in photographic apparatus. James Preston Cribb, 9, Warwick Court, Gray's Inn, London, W.C.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**SHUTTERS.**—No. 12,878, 1905. The invention consists of a clockwork exposing mechanism by which the shutter can be opened and closed at a given time after the movement of an exposing lever, so that the exposure is made without vibration of the tripod or other support, and so also that the operator may be able to include himself in a group. George Andrews, 30, Bosworth Road, North Kensington, Middlesex.

**FILM ENVELOPES.**—No. 10,955, 1905. This invention relates to a light-tight packet for photographic sensitised films, etc. The packet is such that it can be introduced with the sensitised surface inside it, into an apparatus constructed for the purpose, and the enveloping material of which the packet is formed may then be withdrawn from the sensitised surface to expose the latter. The packet consists of two envelopes of suitable light-tight material, such as black paper or card, capable of being slipped one inside the other. Each envelope is open at one edge only, and the film having been placed in the envelope which is to be the inner one, this envelope is introduced into the other one with its open edge innermost. When the packet containing the film has been placed in the apparatus the two packets may be withdrawn and the film left ready for exposure. The main difference between this packet and other forms of enveloping devices is that in the latter either one envelope has been entirely enclosed in the other, or a part of the enveloping material has been connected with the surface during the exposure, occupying space in the magazine into which such surfaces are generally transferred after exposure. To provide for the retention of the film in place while the inner envelope is being withdrawn, the outer one having been withdrawn first, the film may have one or more perforations which are not covered by the inner envelope, and are for the purpose of receiving as soon as the outer envelope is withdrawn, some form of detent such as spring pins carried by the apparatus into which the packet has been introduced. In order to ensure that the packet shall be light-tight the inner envelope may be provided (at that of its closed sides which is opposite to its open side) with pockets of suitable material into which the edges of the open side of the outer envelope may slide. Or the edges of the open side of the outer envelope may be gummed or otherwise fastened to the inner

envelope at this part, and may be cut open before using the packet.  
Oscar Becker, 62, Jesusalemer Strasse, Berlin, S.W., 19.

A French patent, No. 359,218, has been taken out by the Neue Photographische Gesellschaft, of Berlin, for "photographic images which become visible or which change after exposure to light." Bromide prints may be bleached in solutions of copper salts containing small quantities of ammonium, sodium, or magnesium chloride. The colourless images thus produced only return to their original form after considerable exposure to light.

## New Books.

"The Watkins's Manual of Exposure and Development," by Alfred Watkins. Hereford: The Watkins' Company. 1s.

The fact that this is the third edition of this little work is quite sufficient proof that the matter provided by the author is to the taste of photographic readers. It has been carefully revised, partly rewritten, and several additions made, notably a "snapshot beginner's chapter," specially addressed to those who commence photography with a hand camera.

Although many objections have been advanced against it, the factorial system of development has found many followers, and whilst it may be thrown over by the expert worker who strives for effects, there is no doubt that for the beginner it is extremely valuable, as it gives him advice on a point respecting which he has no experience to fall back on. We note that a new method is now published—viz., to dilute the developer with as many times its bulk of water as the factor for one developer, and to immerse a slip of a plate in this dilute developer. The first appearance of the image on the slip will be the full time necessary for the development of the plate in the full-strength developer. The slip is exposed under a grating of black paper in the camera, with the lens pointed to the sky—a plan originally suggested by the author for colour-sensitive plates.

Plain instructions are included for printing and toning P.O.P., and some useful tips are given at the end of the book, in which so far we have only seen one mistake, and that is in the table of diaphragm values, where the old Congress numbers of  $f/10$  as 1 are given, whereas the most recent decision has made the  $f/x$  system the official one.

"Die Künstlerischen Grundsätze für die bildliche Darstellung, deren Ableitung und Anwendung," by C. Baumann. Halle, a/S. Wilhelm Knapp. 5s.

The author in his preface points out that many readers will be surprised to find subjects dealt with in this book which do not appear to belong to Art, and adds that they will soon, however, be convinced that they are essential, for only by Science can Art be placed in that position which it should occupy, and that, after all, a knowledge of nature is Art. No doubt many of the present-day school of pictorial photographers will dispute this; they are not content with Goethe's axiom, "Die Natur ist aller Meister Meister," for they improve upon it so much that one cannot recognise it at all.

Proceeding on these lines, the author explains, first, the phenomena of sight, light, and the formation of shadows and colours; then the lighting in nature and its various effects, the angle of view. Having thus defined the principal laws, he connects them with photography, and gives us a readable treatise from which much can be learnt, not only directly, but also by indirect suggestion of much that is omitted.

"Magnesium Light Photography." By F. J. Mortimer, F.R.P.S. London: Dawbarn and Ward, 1s. nett.

A book on flashlight by somebody who wrote from the results of hard experience has long been wanted, and Messrs. Dawbarn and Ward may congratulate themselves in making this commendable addition to photographic text-books, instead of contributing to the deluge of manuals reiterating the stock beginner's themes in new phrases. By leaving the subject in the hands of Mr. F. J. Mortimer they have not been disappointed in their desire to offer the photographer a reliable guide to work of this kind. It is not a large book, but the text is pruned of redundancies to a degree which might

profitably be imitated more frequently, inasmuch that there are not half-a-dozen superfluous words in the book, except the preface which says nothing, but says it extremely pleasantly, as though the task of filling one page and a turnover did not in any way distract the writer. The chapters are devoted to (1) apparatus and materials, (2) subjects and lighting, and (3) the most suitable methods of treating the exposures in development and printing. Notes on the commercial lamps and powders occupy the author chiefly in Chapter I. In Chapter II. he considers lighting for daylight and other effects. In Chapter III. he gives a series of fireside studies, in a number of cases showing the reader how certain (reproduced) effect was obtained by including a half-ton photograph of the actual arrangement at the moment of exposure and a floor plan of the positions of sitter, camera, lamp, reflector, and background. This feature is characteristic of the value of the book for purposes of self-instruction.

"The Hand-Camera Companion and Guide" is a volume uniform in size and production with the recent "Library" series of "The Practical Photographer," to which it is practically an additional number. It deals very succinctly with the considerations governing the choice of a hand camera of moderate price, saying a great deal on the functions, defects, and advantages of the various parts, and not very much on the photography of common objects with the hand camera. However, that has all been said before in previous issues of "The Practical Photographer" and in other publications. The price of the book is one shilling.

## New Apparatus, &c.

The "Celerex" Shutter. Made by R. and J. Beck, Limited, 60, Cornhill, London, E.C.

In this shutter Messrs. R. and J. Beck have embodied a new and recently patented method of theirs in shutter design to the production of a shutter which should correspond accurately with the speed markings upon it. In the "Celerex" the different speeds are obtained not by putting a greater tension on the driving mechanism, but by applying a more or less powerful brake, but only by increasing or decreasing the size of the aperture by which the exposure is made.

the aperture being enlarged or contracted by rotating a sector plate, the movement of which is directly connected with the scale of the speed numbers. By this device Messrs. Beck provide the user with speeds of 1-10, 1-20, 1-40, and 1-80, in addition to "time" and "bulb" exposures, a sufficient range, it will be admitted, for all ordinary hand camera work. But the most important feature of the

shutter is the accuracy of the speeds which the makers guarantee. Each instrument is tested before it is sent out, and a card of speeds enclosed, showing the difference, usually negligible, from the engraved speeds. In other respects the "Celverex" possesses desirable features. It is thin, light, and therefore may be fitted between the components of a double lens, even of those supplied with the smaller folding cameras. It carries an iris diaphragm, which can be suitably engraved to suit a given focal length of lens, and lastly, the working parts appear to be reduced to such simple proportions that the shutter may be expected to preserve its accuracy of working throughout a protracted period of constant use. The "Celverex" is made in three sizes, for quarter-plate, 5 x 4, and half-plate lenses, at the prices of £1 15s., £1 17s. 6d., and £2 5s. respectively. Messrs. Beck have also a number of their cameras already fitted with it.

The "Elite" Focal-Plane Camera. Sold by the City, Sale, and Exchange, 90 to 94, Fleet Street, London, E.C.

A convenient model of the folding focal-plane camera is supplied under this name, its appearance being generally as shown in the figure. The lens front is drawn forward very conveniently and easily on the jointed struts, which are strengthened with springs at the junctions. The front has a revolving lens panel permitting the rising front to be employed either way of the plate, and like all-metal parts of the camera is inconspicuously finished in black lacquer. The bellows

and covering of the back frame is of black grain leather, the whole external appearance of the camera being handsome. The focal-plane shutter possess a convenient series of adjustments for time and instantaneous exposures, and for altering the width of the slit from the outside of the camera. The complete camera is supplied with three double dark slides and Ross Homocentric lens  $f/6.8$ , for £8 8s. Other anastigmats, notably those of Goerz, are fitted to the camera.

The "Eidoscope" Lens. J. Fleury-Hermagis, Paris. Sole British representative, F. C. Clarkson, 4, Fenchurch Avenue, E.C., and Colchester.

We have received a specimen of one of these lenses from Mr. Clarkson for examination, the one submitted to us being of  $14\frac{1}{2}$  in. focal length and full aperture  $f/5$ , and fitted with iris diaphragm. It appears to be a symmetrical doublet, and is formed of two cemented achromatic combinations. It is said to be intended for "artistic portraiture without retouching," but is different from the anachromats we recently reported upon, in that it is under-corrected for spherical aberration though achromatic, while they were designed to give minimum spherical aberration and were only partially corrected for colour. The effects obtainable by the two types of lenses are therefore essentially different, whether the subject be portraiture or landscape. The apertures of the Eidoscope are marked in accordance with the C.I. system, with the following series of numbers: 0.25, 0.36, 0.50, 1, 2, 4, 8, 16, corresponding approximately to the series  $f/5$ ,  $f/6$ ,  $f/7$ ,  $f/10$ ,  $f/14$ ,  $f/20$ ,  $f/28.3$ ,  $f/40$ . At  $f/5$  the focus is very much blurred by spherical aberration. At  $f/10$  good focus can be obtained in the centre of the field, but curvature of the field is apparent. At  $f/20$  fairly good focus is obtainable over a 10 inch circle, though astigmatism is very much in evidence near the margins. At  $f/10$  to  $f/20$  it is recommended for landscape work, with which neither curvature nor astigmatism are of much consequence, and on small plates, say half-plates, the lens will behave in much the same way as a narrow angle rectilinear if the stop does not exceed  $f/20$ . On a fairly near test object no distortion was

obvious on a 12 x 10 plate. The single combination makes a useful long focus lens of about 31 inches focal length. The particular lens submitted to us has combinations of  $3\frac{1}{2}$  in. diameter, and a flange of  $5\frac{1}{4}$  inches, while the whole objective weighs 3 lbs. 10 ozs. It is the largest but one of the series of form listed, and is, of course, only suitable for use in a very rigidly constructed studio camera. It costs £8 12s. 6d., with iris. The smallest and cheapest lens of the series is of  $7\frac{1}{4}$  inches focal length, and  $1\frac{1}{2}$  diameter, and costs £3 7s. 6d. with iris, and £2 15s. with Waterhouse stops.

Messrs. R. and J. Beck have issued a new and revised edition of what they modestly describe as "a booklet" on telephotography, although its sixty-four pages and numerous plate illustrations on art paper justify a more ambitious title. It is, as a matter of fact, as complete and comprehensive an instruction book in telephoto work as can be bought for a moderate price, and Messrs. Beck's offer to send it post free is one to be embraced.

## New Materials.

THE Barnet Orthochromatic Screen.—Messrs. Elliott and Sons, Ltd., are offering at a low price a well-finished yellow filter put in a metal hood fitted with a spring which enables the filter to be fitted over lenses of several sizes. Tested spectroscopically this filter cuts down most of the blue-violet and ultra-violet, and, tested on a coloured subject outdoors in conjunction with a Barnet orthochromatic plate, all colours except red were well rendered in monochrome, so that the filter and plate are quite suitable for ordinary landscape work. The gap in sensitiveness in the blue-green is noticeable, and we should think that there are sensitizers now available which could be used to fill it up.

MESSRS. WRATTEN AND WAINWRIGHT'S Improved Verichrome Plate.—This plate, tested spectroscopically, shows the common drop in sensitiveness at about 4,900 A.U., but this is less marked than in the usual commercial orthochromatic plate. The sensitiveness then goes on practically evenly to 6,100, with long exposures. Two faint bands appear to indicate that the sensitiveness is conferred by one of the new isocyanine dyes. Messrs. Wratten give away, on request, a pale yellow light-filter made of stained gelatine. Tested on the spectroscope, this appears to cut down most of the blue and violet, and tested on a coloured subject out of doors, giving three times exposure without a filter, we found all colours very well rendered with the exception of reds. These were, however, well rendered when using a deeper filter and increasing exposure ten times. This plate, with the filter supplied, would appear to serve admirably for all landscape work, or for copying any subject in which reds do not occur.

## CATALOGUES AND TRADE NOTICES.

THE trade price list of W. Warren Jepson and Co., Hanover Street, Leeds, which reaches our table, contains, we find, a very full tariff of prices for bromide and other enlarging, with and without finishing, in monochrome, oils, or water colour. Messrs. Jepson illustrate their special lines in enlargements plentifully by half-tone blocks, and exhibit an extensive series of mouldings by the same means. The list is altogether a comprehensive one for all classes of trade work, and the style of its production—which is usually a pretty good criterion—speaks well for the firm's standard of quality.

THE Service Company, 292 and 293, High Holborn, W.C., send us their very full list of photographic requisites for 1906, every page of which specifies and illustrates a large number of apparatus and accessories. The list offers a very large choice in cameras and lenses.

A CIRCULAR of the various forms of assistance offered to designers of post cards, etc., is sent us by Ralph Rutley, 249, The Grange, London, S.E.

THE Bradford Photographic Society has changed its meeting place from the Grammar School to "Ye Mecca" Café, Brook Street, Bradford.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
12.....	Birmingham Photo. Society. ...	Half-day Excursion to Ashow.
12.....	Manchester Amat. Photo. Soc. ...	Outing to Kenyon Peel Hall, and Southwell Cathedral.
12.....	Bristol Photographic Club ...	Trip to Porchury.
12.....	Hull Photographic Society ...	Outing to Beverley.
12.....	Blackburn Camera Club ...	Outing, Great Harwood to Langho.
12.....	Halifax Camera Club ...	Trip to Hardcastle Crags.
14.....	Cripplegate Photo. Society ...	"Photography with the Microscope." Mr. J. Inderwick Pigg, F.R.P.S., F.R.M.S.
14.....	Bradford Photo. Society ...	"Page Croft Pigment Paper." Mr. J. P. Seaman.
15.....	Royal Photographic Soc. ...	"By-paths in India." Mr. F. Dunster-ville, F.R.P.S.
5.....	Manchester Amat. Photo. Soc. ...	"Figures in Landscape." Mr. J. D. Berwick.
15.....	Hackney Photo. Society ...	Excursion Prints Judged and Criticised. Exhibition of Pictures by Wm. Rawlings.
15.....	Cardiff Windsor Amat. Ph. Soc. ...	"A Practical Lesson in Outdoor Photography."
16.....	North Middlesex Photo. Soc. ...	"Isochromatic Work." Mr. J. McIntosh.
16.....	Cricklewood Photo. Society.....	"Cameras and How to Use Them." Mr. Wilfred Emery.
16.....	Everton Camera Club.....	Five Minutes' Lectures.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held May 1, Mr. C. G. Zander in the chair. The fixture for the evening was a demonstration of the making of three-colour transparencies by the Sanger-Shepherd process by Dr. A. Norman. The proceedings can hardly be said to have included a demonstration of the process, a task which is hardly possible before an audience and within the limited time of a little over an hour. Yet Dr. Norman provided a very acceptable substitute by a clever pantomimic presentation of those parts of the process which he was not able actually to carry out before the audience. This he did with such precision in details that the make-believe became almost as convincing as the actual demonstration would have been. Indeed, it can be said that a "demonstration" of this kind may often be more valuable to those desirous of picking up tips in manipulation from a master of a process than a real one, in which the demonstrator is unable to permit more than one or two people to see what he is doing in the sombre illumination of the dark room. Dr. Norman left no trifling point in the making of a Sanger-Shepherd transparency untouched, and his narration of the minutiae of the process, which occupied considerably over an hour, was one proof of the unremitting attention to minute details which is necessary for the successful working of any process of preparing three-colour results by combining component films. At the conclusion of the demonstration a number of very fine photo-micrographs by the Sanger-Shepherd process were shown on the screen, Dr. Norman giving some brief particulars of each. The discourse, when it is published in the Society's "Journal," should supply the most painstaking instruction in the Sanger-Shepherd process which has yet been made public.

Meeting held May 8, Major-General Waterhouse in the chair. A paper by Mr. H. J. Channon was summarised by Mr. S. E. Sheppard. Mr. C. E. K. Mees and Mr. Renwick took part in the discussion. A demonstration followed of "Goldona" by Mr. Green, of John J. Griffin and Sons, Ltd., Mr. A. Haddon giving the results of experiments of his with the paper.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held Thursday, May 3, Mr. W. G. Holman in the chair. A hearty welcome home was given to Mr. A. L. Henderson upon his return from his winter's sojourn in Madeira. Mr. Ferry was elected librarian in place of Mr. Marshall, who has resigned through ill-health. Mr. Ernest Human read a paper upon "Funniosities Heard at a Dealer's Counter," in which he detailed the humorous incidents which lighten the labours of the staff of the City Sale and Exchange in Fleet Street. One of his colleagues was recently asked by a would-be photographer for Ilford P.O.P. It is happened that the firm was out

of stock of the size he required, and he was told so, with the addition that he could supply him with either "Imperial," "Wellington," "Barnet," or others; but these, he said, were of no use, as all his negatives were upon Ilford plates, and no amount of talk would convince him that the plate used for the negatives did not make any difference; his were Ilford, and would not print upon any other than Ilford. It may be wondered what plates he will use when he reaches the gum process. Upon another occasion a Wrench cinematograph had been sent to a customer in Ireland, and a few days later came along a request for a reading lamp, about ten shillings and sixpence. Such a lamp was forwarded, and in reply came a letter saying, "Lamp safely to hand, but it is of no use." We cannot get any light." A letter of enquiry disclosed the fact that he had actually used the reading-lamp in the lantern and tried to throw a twelve-foot cinematograph picture with it! When lenses were being shown to customers the argument was frequently put forward that because a Cooke lens had a flat glass at the back it must perforce give a flatter field than others which were all more or less round. Presumably, the man who uses an iso screen at the back of his lens, must get the flattest of all fields. A customer once asked for blue litmus paper, and upon a book of it being put before him, he replied he wanted 5-4in. size, from which it transpired that he wanted to make blue prints. After some explanations he was prevailed upon to take ferro-prussiate paper, as being nearer the thing he wanted. "I want a 12-foot flash sheet," was the request of a young gentleman one day. It afterwards transpired that he wanted it for a lantern screen, because it gave off a far better light than the linen ones. Another gentleman wanted an enlarger with a cross front, because by its use he was told he could correct any lines out of truth in his negatives. In the case of an air bubble in a Dallmeyer lens it was stated that it did not matter at all in actual work because "it only stopped a fraction of a thousandth part of a centimetre of light." Upon another occasion a prospective purchaser of a £7 7s. Kodak, had had its various points repeated to him some two or three times, when he put his money upon the counter, remarking that it would do. It so happened that there was lying near at hand a mounted print, which the customer picked up, saying, "When I have pressed this, and wound this, I open the camera, and take out a picture like this?" It was again explained to him that the film would have to be developed and printed, to which he rejoined, "Then I'm hanged if I'll have it," at the same time sweeping the cash into his hand and stalking away. Customers are continually asking for that P.O.P. which gives black and white prints with a dull surface. One of these, who was given a gaslight paper, together with some 15 to 20 minutes' explanation of how to use it, delivered a knock-out blow by asking: "Which was the stronger, sunlight or gaslight?" Another, buying a ferrotype plate for squeegeeing his prints, said: "It is better when glazing prints to use an alum bath, is it not?" Upon being told that was so, he asked, "Which do I put into it, the plate or the print?" Mr. Henderson proposed, and Mr. Haddon seconded, a hearty vote of thanks to Mr. Human for an enjoyable evening.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.—Mr. H. Gordon Stollard lectured on "Retouching" on April 26. Many valuable hints were given, and the following points may be noted as of general interest:—

1. When applying the retouching medium see that the edge is softened, otherwise it might show in the print.

2. When working only have a small piece visible, as this conduces to comfort and ease.

3. According to the strength of negative use various surfaces for reflecting daylight.

For dense negatives use a mirror.

For medium negatives use a white board.

For thin negatives use a white dull board.

4. For working by artificial light hang from the retouching desk a sheet of tissue paper, behind which may be placed a candle.

5. A magnifying glass of about 6ins. focal length, large enough for both edges to look through, should be used for small work.

6. Pencils—Hardmuth's or Faber's BBB to HHH preferably to be used in a holder so that a long, fine point can be secured, as this is

essary to enable the worker to see where he is placing the

For reducing densities small retouching knives, costing 6d., and local dissecting knives, both blunt and chisel pointed.

Proof negative as progress is made.

No particular stroke is necessary but that which serves the pose of the moment must be used. On the hollow of a cheek a full method is to make the figure eight horizontally without lifting pencil. The small shadow running from the nose to the side of mouth can be filled in with commas.

Attention should be paid to the catch light in the eyes, which will always be of wedge shape, with the base of the wedge towards source of light.

In working on the eye be careful not to obliterate the red spot the corner.

In portrait negatives the smaller the head the finer the work is to be done.

From time to time, as work progresses, look at the negative in a little distance, and see if defects have been removed and telling secured.

Take out spots first. Then work on the high lights on forehead. Catch the two prominences above the eyes, and preserve the depression which lies between them. The strengthening of the high lights is relief, which is all important.

Texture. This must not be lost sight of, and it should partake the nature of the original. Study good engravings for knowledge.

Lips. See that the high light on the lower lip is present. Just the curve. Remove the shadows which run downwards from the ends of the mouth. Very red lips require the shadow between in lightening.

The hair often comes out without any relief. Keep careful on the method in which the model dresses the hair, and study where the light is reflected.

With the retouching knife many imperfections can be erased, to accomplish this successfully much practice is required. Obtrusive high lights can be removed, a spotty background simplified. That protrude a little too much, or are too large, can be reduced,

THAMPTON CAMERA CLUB.—On May 7, Mr. J. Randolph lectured "Stereoscopic Vision in Relation to Photography," his discourse being the outcome of experiments made with the object of securing on one print the effect produced by the use of the stereoscope from double picture. After setting out the laws underlying the effect of light upon the single eye and the pair of eyes, the lecturer detailed the measure of his success. He found that it was possible by the use of a single lens of the focal length of thirty inches, masked so as to serve as a twin lens, to bring the object into focus upon a single plate, but that the portion of the sensitive plate brought into stereoscopic focus was comparatively small, the plane being very limited. The lecturer related his efforts with prisms and reflectors, which had brought him little satisfaction, and suggested that with further perfection in the method which had been partially successful, something much better might be done. A discussion ensued, various suggestions being considered.

COURSE of seven lecture demonstrations on three-colour and monochromatic work will be given on Thursday evenings, from May 10 to June 14, inclusive, at the London County Council School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C. The lecturer is Mr. A. J. Bull, assistant to the principal. The course includes:—Introduction: Nature of light and colour, selective absorption and other causes of colour effects, the spectrum, use of ordinary colours, primary colours, properties of orthochromatic plates and methods of testing, safe lights for the dark-room, use of light filters, orthochromatic photography, three colour photography by the additive method, three-colour photography by the subtractive method, nature of best reproduction colours and negative records, adjustment of colour filters to plates, effects of incorrect filters and plates, position of the filter, three-colour negative making, details of the indirect method, avoidance of screen pattern, a direct method by the use of a collodion emulsion and the dry plate, fine etching, printing, four-colour processes. Admission is free to students of the school; to others the ticket for the course costs only 2s.

## Commercial & Legal Intelligence.

**DRY Mounting.**—In the Chancery Division, on April 30, the case of the Adhesive Dry Mounting Company, Ltd., v. the Adherent Film Company came before Mr. Justice Kekewich. Mr. Coldridge, who appeared for the plaintiffs, said the defendants had put in evidence which he had not seen, and which raised a serious question as to validity. In the circumstances, if the defendants undertook to keep the usual account, he would not ask for anything more on this motion, and the matter must stand until the trial. Mr. Justice Kekewich said he had nothing to do with that. There would be no order on the motion, except that the costs of the motion would be costs in the action.

**THE Viscose Patent.**—The Judicial Committee of the Privy Council (Lord Macnaghten, Sir Andrew Scobie, Sir Arthur Wilson, and Sir Alfred Wills) on Wednesday, May 2, gave its decision in a petition by Messrs. C. F. Cross, E. J. Bevan, and Clayton Bradle for prolongation of the term of letters patent No. 8,700 of 1892. The invention consists in the production of a mouldable cellulose material by mercerising fibrous and cellular materials, and while in this condition treating with carbon bisulphide. Various projects had since the invention been formed to exploit it, and in 1902 these were centralised and combined in one called the Viscose Development Company, Ltd. A great many difficulties and trade prejudices had to be overcome, and now, as the patent is about to expire, the applicants would lose the advantages which they believed they were entitled to. Sir William Ramsay, F.R.S., and others had given evidence on behalf of the petition, and certain objectors had withdrawn their opposition. Lord Macnaghten intimated that the Committee would humbly advise His Majesty to prolong the patent for five years, the longest term that had been granted of late years to an invention of conspicuous merit.

**ALLEGED Dishonest Assistant.**—At the Westminster Police-court, on Thursday in last week, F. T. Gosling, of Nigel Road, Peckham Rye, lately an assistant in the optical and photographic department of the Army and Navy Stores, was formally examined on charges of stealing and attempting to steal from his employers. Mr. Jenkins was counsel for the prosecutors, and Mr. Henry Curtis-Bennett appeared for the prisoner, who was alleged to have pursued a very artful method of manipulating the triplicate bill forms which he made out, and presenting one as a form of receipt for money to the customers on whom he called. The magistrate declined to allow the prosecution to supplement their evidence, and committed the prisoner for trial for falsification of accounts. Bail was allowed.

**TRAVELLING Photographers.**—Edward Pronk, who was respectfully dressed, and said he was a photographer from London, was charged at Dudley Police-court with stealing a gold ring, value 50s., from the Woolpack Inn, belonging to Florence Murphy, the landlady. Pronk and Thomas Beaumont, also a travelling photographer, were charged with stealing a silver watch and gold-plated chain and a gold brooch, value £2 15s., the property of a domestic servant at the Woolpack Inn. On April 21 the servant saw Pronk come down the stairs at the Woolpack Inn and leave the public-house. Shortly afterwards the articles enumerated were missed from the bedroom. The same evening Pronk attempted to pledge the ring, and this led to his arrest at his lodgings in Stone Street the following morning, when he told Police-constable Stevens that he bought the ring from a man in the street. On the strength of a statement Pronk subsequently made, the constable arrested Beaumont at Kidderminster, but Pronk subsequently admitted that his statements as to Beaumont were not correct. Beaumont was discharged, and Pronk was sentenced to four months' hard labour.

**APOLLO Art Association, Limited.**—This company has just been registered with a capital of £3,000 in £1 shares, to take over the business of photographers, photographic enlargers, and moulding importers carried on by I. Vogel, H. Pollak, J. L. Rosenheim, and J. Lauer, at 31, Derby Road, Nottingham; 14, Norfolk Street, Sheffield; 17, Oxford Road, Manchester; 12, Bond Place, Liverpool; and 194, West Regent Street, Glasgow, as the "Apollo Art Association." The subscribers are:—H. Pollak, I. Vogel, J. Rabinovitch, G. S. O'Rourke, C. E. Woodham, J. Lauer, F. Jackson. No initial public

issue. The first directors are H. Pollak and J. Lauer. Qualification, twenty-five shares. Remuneration as fixed by the company. Registered office, 31, Derby Road, Nottingham.

## Dews and Notes.

THE exhibition of photographs by members of the Birmingham Photographic Society, now on view at the Royal Photographic Society's House, will remain open daily from 11 a.m. till 5 p.m. till Saturday, June 16. The public are admitted on presentation of visiting card.

THE Charles Urban Trading Company have added to their cinematograph triumphs another in the shape of a film of the Hackenschmidt v. Madrali wrestling contest at Olympia on April 28. The exposures were made entirely by artificial light, and the result is a very fine film indeed.

ROBBERY at Llanelly.—Llanelly police are investigating a robbery which occurred last week, when the premises of Mr. Griffiths, photographer, Market Street, Llanelly, were entered and the sum of 28s. was taken, in addition to a lens valued at £15.

DEATH of Mr. George Bruce.—We are sorry to hear of the death, on April 19, of Mr. George Bruce, of Duns, a very old and respected member of the photographic profession, and one who, without ostentation, contributed to the elevation of the craft as a whole. Mr. Bruce's name is perhaps familiar to readers of the JOURNAL from his practice and advocacy of collodion paper. He adopted this form of printing at a very early date, and throughout his business career employed no other. A number of Mr. Bruce's prints which we once inspected thirty years after their manufacture entirely justified the claims of permanency which he and others have made on behalf of collodion paper.

WITH the Prince in India.—The photographer of the "Daily Mirror," who, at six hours' notice, left Paris to accompany the Prince and Princess of Wales to India, unburdens his soul to readers of the "Mirror." "I exposed over 1,500 plates during the tour, and photographed the Prince and Princess themselves more than 500 times. I am afraid they must have got heartily sick of seeing my camera pointed in their direction. Indeed, on one occasion, at Hyderabad, the Prince, who had faced a battery of cameras for hours, grew tired of being snapshotted. 'Leave your camera behind you,' he said, calling me on one side. 'We are going tiger shooting. Come with us and have a holiday.' And so I journeyed with the Royal party, and had a fine day's sport in the jungle. The Princess, who is greatly interested in everything connected with photography, frequently asked me how my photographs were turning out, and on several important occasions her Royal Highness asked me to be particularly careful with the photographs. Then she would ask to see proofs, and several times I made her copies of the photographs on postcards. These she used to send home to her children. My principal difficulty, of course, was getting the photographs off to London as quickly as possible. One one occasion, for instance, when I took photographs of the Prince watching an elephant drive in the jungle some fifty miles from Mysore, I sent my undeveloped negatives off by special runners within half an hour of the time they were taken. The runners carried them fifty miles through the jungle to Mysore, and from there they were carried on an express train to Bombay, nearly a thousand miles away. There they caught the P. and O. mail steamer for Brindisi and were brought straight to London by the overland route. Not an hour was lost on the journey, and as a result the photographs appeared in the "Daily Mirror" within seventeen days of the date on which they were taken in the Indian jungle."

CROYDON Camera Club.—A notable fixture even amongst the programme of good things which the Croydon Society sets before its members is down for Wednesday next, May 16, at 8 p.m., when Mr. C. E. K. Mees will read a paper on "Orthochromatic Plates and Filters." Synopsis: The curves given by plates with and without filters, and their approximation to the luminosity curve; the multiplying factors of filters; isocyanine bathed plates and their possibilities; rapid exposures through filters; a new panchromatic plate.

The paper will be illustrated by diagrams, lantern slides, and projected spectra.

THE Lizars' £200 Competition.—The full prospectus of the above competition, which is now obtainable from the head office of Messrs. Lizars, at Buchanan Street, Glasgow, or from the branches in London, Liverpool, Edinburgh, Belfast, and Aberdeen, shows the great distribution of the money prizes which has been secured by the organisers. There are nine classes, each of which is divided into two sections, to each of which from four to eight prizes are to be awarded. Thus the "plums" of the competition cannot go to a fortunate few, and for this reason amateurs, particularly those of only a few years' standing, should view the competition favourably. There are special classes for those who purchase during 1906, and special sections for those who have never gained an award in any competition which, of course, does not prevent them from entering in any of the other classes, but gives them a better opportunity of success. An exhibition will be held in the Royal Institute of Fine Arts, 279, Sauchiehall Street, Glasgow, from the 14th to the 26th of January, 1907, inclusive, and entry forms must be returned not later than January 10, 1907.

MR. C. S. BAYNTON (with a "y") has our sympathies for the way in which printers have been taking liberties with his name. The R.P.S. catalogue of the Birmingham photographs at Russell Square prints him as "Baignton." We confess to making an imperfect correction of this into "Bainton," but we see a contemporary has improved the R.P.S. version to "Baignnton."

THE death is announced of Mr. A. Booth, late of Booth and Bowman, trade printers, Stapleford, Nottingham. The deceased was in his fifty-seventh year.

THE Queen's Photographs.—Some most interesting pictures taken with the Kodak by her Majesty the Queen are to be published in "The Gentlewoman" as free supplements, the first to be given with this week's number. The pictures, which are taken variously at Gibraltar, Kiel, the Highlands, Wurtemberg, Sandringham, Wind Castle, Marlborough House, and on board the Royal yacht, bear full evidence of her Majesty's particular skill as an amateur photographer.

A RELIEF Fund for Californian Photographers.—The recent gigantic disaster in San Francisco has speedily aroused the personal sympathy of the photographic fraternity in America. An emergency committee called by the Professional Photographers' Society of New York has established a national fund by a popular five-dollar subscription. The metropolitan section has raised 5000dols. from the photographers of Greater New York within twenty-four hours, and the Albany section P.P.S. of New York has agreed to contribute a minimum of 200dols. We believe that the American spirit of self-reliance will not sanction any appeal for help from those outside the United States, though we have no doubt, also, that any donations from Americans in England or from those here who have made friends on the other side of the Atlantic would be gratefully received by the treasurer of the committee, Joseph Byron, 53 West 32nd Street, New York City.

A POSTCARD Combine.—A society for the protection of picture postcard manufacturers' rights has been formed under the title of "Postcard Industry Defence Association." At a meeting called to discuss the aims and objects of the association, the industry was represented by Messrs. Alexander and Co., Blum and Degen, Bamford and Co., Collectors' Publishing Company, Delittle, Fenwick and Co., Langsdorff and Co., Frankel and Co., Giesen Bros., and Co., F. Hartmann, Maxim Niven, Pictorial Postcard Company, the Regent Publishing Company, Raphael Tuck and Sons, etc., the chair being taken by Mr. E. W. Richardson (proprietor and editor of the "Picture Postcard.") For the post of solicitor to the society, Mr. G. D. Turner, of Messrs. Ashley and Turner, of 9, Charles Street, Hoxton, N., was appointed. Mr. Maxim Niven was elected secretary, and the following gentlemen were proposed as vice-presidents: Mr. Carlo Degen (Blum and Degen), Mr. E. von Dolffs (a member of Messrs. Langsdorff and Co.), Mr. Karl Giesen (Giesen Bros.), Mr. Hael (the Rotary Photographic Printing Company), Mr. J. Mischel and the principals of Messrs. Davidson Brothers, W. Ritchie and Sons, of Edinburgh, and Valentine and Sons, of Glasgow.

first business meeting of the association Mr. E. W. Richardson unanimously elected president. Offices have been opened at Messian Buildings, City Road, E.C., where those interested can apply for information.

**COPYRIGHT in Canada.**—Henceforth anyone reproducing without authorisation in the Dominion of Canada any copyrighted picture or work of art originating from France will be liable to action under the international copyright law, which was agreed at the convention of Berne in 1886. Such is the effect of a judgment rendered recently by Judge Fortin, of the Superior Court of Montreal. The case was that of Jules Mary, a French novelist, sued the Compagnie de Reproduction Littéraire, of Montreal, for the piratical publication of one of his works, "Tante Berceuse." Judge Fortin ruled that England, being one of the contracting nations at the convention of Berne, the international copyright law is applicable to all the British colonies, and that consequently the plaintiff was protected in Canada, although he had not complied with the requirements of the Canadian copyright law. The case was instituted by M. Mary as a test case at the instigation of a Canadian organisation known as "The Syndicate of Literary and Societies for the Protection of Intellectual Property." For many years it has been the practise in Canada to produce, either in book form or by serials, copyrighted French works without authorisation from the authors, but if this decision is held an end will be put to such literary piracy.

**THE "Halotype,"** writes the "Photo Era," is a coloured photograph, so called from the name of its inventor, Mr. J. B. Hall. The process consists in printing two paper positives from the negative, rendering one transparent by the use of dammar varnish, painting the other, and placing the transparent print over the painted one in exact registration. The picture is then backed, covered with a sheet of glass and the edges bound together with a partout binding. Anyone who can use a brush can paint the picture, as little or no skill is required, the paint being put on only in washes, without any attempt at shading. The shading detail is produced by the lines in the transparent picture. The picture, toned and dried, is laid on a sheet of glass on which has been rubbed a little glycerine. It is then varnished with dammar varnish and left to dry. If one coat does not make it transparent, a second is applied. Another way to produce a transparent print is to apply the print to glass and remove the paper, leaving the picture on the glass. Take a spoiled negative the size of the print, rub it with a wet sponge with French chalk to remove any possible traces of grease. Varnish the glass with a varnish made of 1 oz. of turpentine and 2 oz. of spirits of turpentine. As soon as the glass begins to set, take the print, which must be thoroughly blotted of the moisture from the face, lay it face down on the glass and squeegee into place, taking special care that no air remains between the glass and the picture. The paper can now be removed by rubbing it gently with the fingers, moistening it with a wet sponge as it dries. When the paper is removed, varnish the film and set it away to dry in a place free from dust. One can now paint directly on the back of this picture. The colours which correspond to the objects represented. No special shading is needed. If water colours are used, mix with these white to give them body, but oil colours work the best and give the most satisfactory results. While these pictures are mainly not "high art," they are often very attractive little souvenirs, and are very appropriate as name cards for a company which has enjoyed an outing together, and of which the picture perpetuates the memory.

**MR. DUDLEY BUXTON, D.Sc.,** has been elected chairman of the Council of the Selborne Society for the ensuing year, during which the society will attain its majority, having been founded in 1885. On May 25, by the kindness of the Civil Service Commission and Majesty's Office of Works, the annual soirée will be held in the offices of the former, in Burlington Gardens, in the buildings which were formerly those of the London University. The president, Lord Avebury, will preside, and deliver an address, while the evening will be an important exhibition of microscopes and natural history specimens. Members may obtain their tickets from the general secretaries, or, in the case of those who are not attached to any of the branches, from the hon. general secretary, Mr. Wilfred Mark

Webb, at 20, Hanover Square. Visitors wishing to be present can only obtain tickets through members.

**MR. WILLIAM BUFFUS,** who has lately returned from Johannesburg to take over the Draycott Galleries (late Barrauds'), at 263, Oxford Street, is the subject of an interview in the current issue of the "African World," where reference is made to his active photographic career in South Africa.

**THE Practical Correspondence College,** Thanet House, Strand, have secured the services of Mr. Ward Muir to conduct for them a postal course in press photography. The course aims to teach how to take photographs suitable to sell to editors, what to take, how to approach editors, what editors to get at, etc. It is intended to appeal either to people who want to make press photography their life profession, or to those who simply want to earn a little occasional money with their cameras, or to make the hobby of photography pay for itself. Mr. Ward Muir has done a good deal of press photography from time to time, and knows the subject both from the editorial and from the contributor's point of view.

**PEROSI and the Cinematograph.**—Dom Perosi, like other composers, has fallen foul of the cinematograph. Some days ago (writes a correspondent of the "Globe") a flaming poster in Rome announced, in large letters, a performance on the cinematograph, and by "kind permission of the composer," of Perosi's "Life and Passion of Christ." Perosi saw the poster, and as the announcement of the composer's "kind permission" was news to him, he promptly called for explanations. These the proprietors of the cinematograph were unable to give, and the posters had to be withdrawn, but behind this there lurks the shadow of litigation over the question of composer's rights.

**THE Academy.**—Were it not for the presence of works as notable as Franz von Lenbach's "Prince Bismarck," "Frau Merk," and "The Artist with his daughter Gabriel," or Fritz von Kaulbach's "Fraulein F.," and "Professor Friedrich Kaulbach," the show (writes the "Globe") would scarcely be worthy of attention—they give it some measure of distinction. There are a few pictures, besides, which have passable merit, August Fink's "Summer Evening," A. W. von Kowalski's "Homeward Bound," Ludwig von Löffitz's "Orchard," Carl Marr's delicate "Portrait of a Girl," Josef Wenglin's "On the Banks of the Isar," Ludwig Wilbroder's "Evening on the Eider," and the rather clumsily painted but effective "Cattle," and "Stubborn," by Heinrich Zügel; but these can hardly be reckoned as sufficient to leaven properly a collection of nearly three hundred works. A protest must be made against the inconvenient arrangement of the exhibition; no attempt has been made in the hanging to follow the order of numbering in the catalogue, and the result is inextricable confusion.

**PHOTOGRAPHIC Survey of Essex.**—The annual report of the Council of the Essex Field Club complains that while the quality of its members is excellent, their number is not what might be expected in a large and populous county. To anyone with the slightest leaning towards natural work, or antiquarian research, the facilities and enjoyable excursions offered by the club should certainly appeal. This is the first year of existence for the Field Club's child—the Photographic Survey and Record. The council express their thanks to the Woodford Photographic Society, who have contributed a set of 200 prints, comprising the survey of Woodford. The council add: Fortunately this society commenced the work several years ago, and some of the prints record parts of the district, the aspect of which has since been completely changed in giving place to modern requirements. This only emphasises the necessity of record work being proceeded with without further delay.

#### FORTHCOMING EXHIBITIONS.

April 27-May 27.—Northern Exhibition (Manchester). Sec., G. M. Morris, 9, Chandos Road, Chilton-cum-Hardy, Manchester.

May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

May 15 to 17, Clevedon Photographic Society. Last day for entries May 9. Secretary, Rev. E. H. Sandford, 18, Hallam Road, Clevedon.

May 17 to 25.—Warrington Photographic Society. Entries close May 7. Secretary, B. C. Smithson, 13, Chester Road, Warrington.

## Correspondence.

\*• Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*• We do not undertake responsibility for the opinions expressed by our correspondents.

### THE MOTION OF THE SIMPLE PENDULUM AND SHUTTER SPEEDS.

To the Editors.

Gentlemen,—There are one or two points in Mr. Collingridge's interesting article on the above subject in your current issue that seem to demand further explanation than they there receive.

It is stated that the approximate formula  $T = 2\pi\sqrt{\frac{l}{g}}$

"is only good enough for such short swings that would be quite useless for shutter-testing." But consider the case of a half-seconds pendulum (i.e., a pendulum which executes a "swing-swing" in two seconds) swinging through a complete arc of 6deg. The bob of such a pendulum would oscillate through an arc of over 4in., which would surely afford a large enough motion for purposes of shutter-testing, provided the motion were photographed full size. Moreover, the time of swing through such a small arc is given sufficiently nearly for any practical purpose by the above-quoted simple formula. Or, to put the matter otherwise, the value of the

correcting factor  $\left(1 + \frac{1}{4}\sin^2 \frac{\beta}{2}\right)$  quoted by Mr. Collingridge differs from unity in this case by only '0007.

It is not quite clear how Mr. Collingridge intends his diagram (p. 350) to be used for purposes of shutter-testing. Suppose the streak of the pendulum bob on the plate corresponds exactly with the first 5deg. of arc from the limit of swing. Then the shutter speed would, of course, be .147 seconds. But if the photographic streak corresponds to the whole of the first 5deg. interval of arc and a fraction of the second 5deg. interval, how is the shutter speed to be deduced in such a case?

I must confess I do not see how the *exact* times of passing over the successive 5deg. intervals of arc can be arrived at. As is shown in the early part of the article, the velocity acquired by the bob in falling from  $\beta$  to  $\theta$  is

$$V = \sqrt{2gl}(\cos \theta - \cos \beta)$$

Writing  $\frac{ds}{dt}$  for V, and  $l d\theta$  for  $ds$ , we have

$$\frac{d\theta}{dt} = \sqrt{\frac{2g}{l}}(\cos \theta - \cos \beta)$$

an expression which, so it seems to me, cannot be solved (i.e., integrated) by the usual methods without simplifying assumptions. Might it not have been well to indicate that the table of times of passage over the 5deg. intervals gives only approximate results?

DOUGLAS CARNEGIE.

Blackheath, S.E.

### THE THEORY AND PRACTICE OF INTENSIFICATION.

To the Editors.

Gentlemen,—There are several points in Mr. Baker's article on the above, other than those raised by your correspondents of last week which require some explanation.

On p. 264 he tells us that the action of mercuric chloride "is to form a surface coating containing silver chloride," yet eleven lines lower down he says "each atom of silver by this operation becomes richer by one more metallic atom, and, with the larger grains, which are possibly metallic on the outside surface and subhaloidal within, etc."

As regards the action of ammonia on the bleached image, this was definitely settled by Mr. Chapman Jones in 1893 (Chem. Soc. Ind., vol. 12, p. 983), and he came to the conclusion that the black image was a double compound of  $\text{NH}_2\text{AgHgCl}$  and  $\text{NHAgHg}_2\text{Cl}$ .

This was confirmed by Leteur (Compt. Rend., January, 1900, p. 2) and by Novak (Eders Jahrbuch, 1901, p. 254), who by chemical analysis finds that the weight of silver chloride is 0.233 of the whole compound. Mr. Baker's statement that the silver chloride dissolved and  $\text{NH}_2\text{Hg}_2\text{Cl}$  forms the image requires confirmation.

As regards the action of sulphite, this was fairly definitely settled by Mr. Chapman Jones ("Photographic News," 1890, p. 100), and has been confirmed by Valenta (Phot. Kor., 1902, p. 513), who undertook the analysis to prove Hauberrisser's statement to be absolutely without foundation, and Valenta states that with sufficient sulphite and sufficiently long action the whole of the chloride is decomposed.

The action of thiosulphates was definitely settled by Valenta also (Phot. Kor., 1903, p. 302).

No mention is made of the use of mercuric chloride and potassium bromide, although it has been proved by H. W. Bennett ("Photographic News," 1902, pp. 358 and 376) and Eder (Phot. Kor., 1900, p. 100) that it gives more intensification than when a chloride is used.

At the bottom of p. 265 it is said—"further experiments, which a longer bleaching was given, etc." Are we to infer from this that in all the experiments the actions were merely allowed to continue as long as the author thought fit and not to their bitter end? If this be the case they are absolutely valueless.

With regard to the chart on p. 266, showing the action of sulphite (Fig. 4), I am not much interested whether the readings are H and D densities or some specially discovered for the occasion, but I would like to point out that if this is a chart of the table immediately below, it is absolutely false, no matter what the densities are, for if the upper end of 1 represents 21, then 2, which should be 27.1, cannot possibly lie so close. If, however, it is intended to represent 17 and 23.1, then it is also false on the same reasoning. In the face of this, what reliance can be placed on any of the diagrams?

We now come to p. 284 of the issue for April 13, where the author deals with uranium and refers to Otterberg. This paper (Bull. Soc. Chimique, vol. 24, p. 355) gives *absolutely the reverse* of what Mr. Baker states. Excess of ferricyanide gives a red image, which has the formula  $\text{K}_4(\text{UO}_2)_2(\text{FeCy}_6)_2$ , whilst excess of uranium gives a brown compound, which has the formula quoted.

From a practical point of view, would it not have been well to point out that the mercuric iodide intensifier, when used as advised (p. 309), gives images which turn yellow very rapidly, and is not the whole of the intensification removed by hypo?

As regards the copper bromide, surely ten minutes' washing is too long in practice?

In the uranium formula (p. 309) we have a different amount of acid from that advised on p. 284.

With regard to the last bath on p. 310, containing copper chloride and hydrochloric acid, if the title is intended to represent the action, surely it is a "terminological inexactitude," because so far as I know cuprous and silver chlorides would be formed. Besides that, it leads to confusion, for since 1883 (Eder's Handbuch, 1883, p. 180) an acid bichromate solution has been known by this title, and as Messrs. Welborne Piper and Carnegie prove that with such a mixture there is no intensification, it seems but reasonable to suppose that there is not chromium precipitation in the film, but that, as the above experimenters state, a photochloride of silver only is formed.

It may possibly be of interest to note that in abstracting a previous article by Mr. Thorne Baker on the same subject, the "Chemiker Zeitung" (No. 27, 1905, p. 415) adds an editorial note to the following effect:—"In the treatment with permanganate and hydrochloric acid there is only a brown coloration if excess of permanganate is present, and this acts as an oxidiser on the gelatine, otherwise with sufficiently long washing pure white plates will be obtained; the slight intensification which actually takes place is perhaps caused by a pigmentary image (Farbstoffbild), produced by the developer. In the treatment with chromate and hydrochloric acid there is formed with silver chloride some chromate of chromium oxide, which, however, is decomposed by long washing, so that here also the plate appears quite white; the use of calcium chromate is purposeless. Potassium bichromate gives the same result."

There are several other points in Mr. T. Thorne Baker's article

might deal with, but as I am not anxious to enter into a controversy, I leave your contributor and your readers to digest it at their leisure.—Yours faithfully,

E. J. WALL.

p. May 5, 1906.

### MEASURING SHUTTER SPEEDS.

To the Editors.

Gentlemen,—It was with much interest I read your article on the pendulum given in your issue of last week. It is a clear and instructive statement, and of no small practical value, giving data embracing the angles of movement required when the pendulum is used in a system of shutter speed testing.

I am particularly interested to note that by this system, in the opinion of "a most accurate determination of shutter speed made."

In your correspondence columns of the same paper there is a letter from Mr. Bosanquet, in which he sums up the whole controversy of the few weeks, and deals with the various formulae that have been submitted for calculating the shutter speeds. He clears up the dispute in a most lucid manner, and as I benefit by having elements confirmed, I am grateful to him for his skillful opinion.

By his correction to the formula you gave, a result is arrived at which agrees with the figures as produced by my formula. I failed to understand how that formula should give the shutter speed, and I debited to him for clearing up the mystery and confirming the correctness of my results. I certainly had not gathered that the formula was only applicable if measurements were taken in feet.

Ratio, 7.5, he arrives at, as a correction in your formula is, I think, measurements I have taken, to be exactly as he states it; but I shall allow me to point out that the ratio is between the length of the camera and the long arm of the compound pendulum, and is not that of the relative lengths of the two arms. The camera may be raised or lowered on the upper arm, and the rays of the exposures still have the same divergence on the plate without altering the ratio.—Yours faithfully,

Lodge, Blackheath, S.E.

ARTHUR A. WATKINS.

May 7, 1906.

### PHOTOGRAPHING THE DEAD.

To the Editors.

Gentlemen,—I could not help smiling when I read in a recent issue the strictures passed upon the samples of photographs taken of the deceased unknowns for the identification collection of the police. I can imagine the tender care and attentive treatment cases would receive at the hands of (for example) the president of the P.P.A., or even of the artist Jaconette. No doubt he would spend an hour or two in posing and lighting, for mortuaries are queer studios, and there is generally a too willing helper to assist. Now what really does one expect when you receive a command?

Many years ago I had the work of the R. Division of Police to do, and my cases were mostly described as "found drowned"—poetic descriptions requiring an acquaintance of short duration and a short memory. Some of the cases linger still in my memory, and they are typical of very many.

I must tell you that soon after I became an unofficial member of the photographic club, my enthusiasm for the work began to decline, and I was fairly well fed-up with tasty jobs. For example:—The head and shoulders of a man suspended from the wall by a rope (the lower portions and limbs had disappeared in an explosion). A man found by reapers in the standing corn supposed to have been asleep four or five months (readily believable).

A black seaman suffocated in a coal bunker. Etc. etc.

After a bit I began to think I was selfish to do all the work myself, and gradually enticed my learner to accompany me on these lovely expeditions to the dead house, and, after much labour, induced him to do the work he liked the work, and gradually, with every semblance of interest, dropped out of going at all. Everything went well for a while, though my assistant could never be induced to do the room work alone. One well-remembered day he returned to work looking very scared, and said his sister had brought a message

asking him to return home at once because his mother had had a side-slip, and he was wanted for repairs (I do not remember which). "Where is the camera?" I asked. "On the top of the body at the Deptford Mortuary," he replied. "Man or woman?" I asked. "I don't know," said he; "I didn't stop to inquire." I sent him home and started off myself as quickly as possible to rescue the body from being over-photographed. I found the attendant had picked my camera off the body and placed it in the only dry spot available—i.e., an old coffin. "What have you got there?" I asked, casting an anxious glance at a mountain covered with a white sheet. "Oh it's all right; I don't think it will pop just yet," answered he. When the covering was removed I found it was the body portion of a man very greatly swollen (recovered after a six or seven weeks' cruise in the Thames), the lower extremities having been annexed by rats.

I now felt comforted by the previous assurance of the attendant, but, to prevent unpleasant surprises, kept religiously behind the camera. Now, sir, I must own I had no appreciation of the subject whatever, a subject that was being constantly doused with water from an old beer-can, a subject nasty enough to cause forty side-slips. You say "they ought to show the shape of the head and the appearance of the person in life!" Let me tell you in the large majority of cases this is quite impossible. Many may not be touched because they have been operated upon, and generally the photography has to be done at a minute's notice after the inquest, light be what it may, and for accommodation just about enough room for self and sitter, and as for doing more than photograph £5, let me invite you to try it. The price paid in my time was 21s. for twenty-four cartes de visites (prints mounted). Now it is 12s. 6d., and I am told it is jumped at. Let 'em jump! I think it a horrible business, and I should be interested to see the results of a good class artist, with the beautiful (or otherwise) surroundings—where the unknown was found—given in.

I am inclined to think both yourself and the coroner would still be unsatisfied.—Yours very truly,

R. LANG SIMS.

437, Brixton Road.

### THE THEORY AND PRACTICE OF INTENSIFICATION.

To the Editors.

Gentlemen,—I am obliged to Mr. Welborne Piper for drawing attention to apparent discrepancies in my articles on intensification; he has evidently taken some of my phrases too literally. For example, when I used the term "precipitated chromate" I, of course, meant the product precipitated from the chromate solution by means of the action of the silver image. I read Messrs. Carnegie and Piper's articles when they were published, and again before writing the article referred to, and I do not think my statements disagree from the facts we already know about chromium intensification. Whether any molecular relationship exists between the oxide precipitated and the reduced silver particles is still a matter of theory; I do not think the two compounds combine chemically, but am quite willing to alter this opinion on seeing definite analytical proof.

The permanganate process I can certainly recommend from considerable experience, and cannot account for Mr. Piper's non-success with it.

Intensification by rehalogenising the image and exposing it to light was suggested in 1902-3 by some Continental writers, whose work I abstracted at the time for one of the English photographic papers. I cannot find the reference at the moment of writing, but will inform Mr. Piper when I do find it.

In again thanking Mr. Welborne Piper for contributing his interesting letter, I would like to draw attention to the great advantage of communicating personal experiences and ideas after the appearance of articles on any subjects of a debatable nature, especially when unaccompanied by the antagonistic tone which seems inevitably to characterise a criticism. The experience of different individuals vary so greatly in photographic work that personal experience is not always a criterion.—Yours, etc.,

T. THORNE BAKER.

7, St. James's Avenue, Anson Road, Cricklewood,  
N.W., May 7, 1906.

## Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.O., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- H. Giles, 121, Lammas Street, Carmarthen. *Photograph of General Mackinnon Unveiling the New Monument, Carmarthen.*
- A. M. Breach, 44, Milward Crescent, Hastings. *Photograph (Combination) of the Burning Ship "Laquo" off Hastings. Seven Different Views on the Post-card, Coloured in Photo Tints by Hand.*
- J. Bishop, Burford House, Tudor Terrace, Aberdare. *Photograph of the Grave of the late G. Lloyd Covered with Flowers.*

### PAINTING REGISTERED:—

- Miss J. E. Corrie, Itchen Abbas, Alresford, Hants. *Painting, Miniature on Ivory of Pope Pius X., Signed by Himself.*

J. H. (Burnley).—We cannot say, as most of this business is done through the English houses handling the cards or taking orders for them. You will see their advertisements in past issues of the JOURNAL.

NEW READER.—You do not say what the difficulty is, but we suppose it is halation. You may find it necessary to put a second backing on the plates. The commercial backing is not sufficient for very strong light through windows. If you desire to get a colour-correct rendering of the windows, you must use an ortho. plate, and a deep screen, and in this case the backing must be black. You would do well to read the pamphlet of Messrs. Wratten and Wainwright, to which we referred last week.

STORING NEGATIVES.—In order to be business-like, I wish to keep books in which would be recorded names of sitters and numbers of negatives. (1) How is a negative numbered and when? (before or after development?) (2) How are name, number, and order entered in book at time of sitting? (3) How is negative number recorded whilst printing, and when print is mounted? (4) Is there any book which guides photographers in this matter?—W. G. C. (1 and 3) If the number is printed near the edge of the negative, with type such as that in the "Nameit" outfit, it will appear on the prints, and will serve to identify them up to the time of mounting. We should not advise you to allow any reference number to appear on the mounted print. The back of the mount is the proper place for it. (2) The best system of keeping an account of sitters, orders, negatives, stock, etc., is the card index. We believe Messrs. Houghtons can give you particulars as to its adaptation to particular cases. (4) None that we know of.

TONING BATH.—We are much interested in your failures, and shall be obliged if you will let us know whether you have been using sulphide toning for bromides. We should also like to see some of the paper before you print on it. Have you been intensifying your negatives with mercury? It is obvious from the fact that you meet with the same failure on different papers that it is not the fault of one particular make. It is also obvious from the appearance of the small unfixed strip that the fault lies in some outside cause. Certainly on this we can see a distinct finger mark in the mother-of-pearl colours, which you complain of, which rather looks like injudicious handling. We should have said off-

hand that the paper had somehow come into contact with cutting board or something contaminated with hypo, but seems to be put out of court by the fact that you are not alone sufferer. Let us know whether you cut up your own paper, the age of it if you can.

PHOTOGRAVURE.—Will you kindly let me know through the medium of your paper: (1) Which book you could recommend to a beginner taking up photogravure? (2) If you know any one or firm who could give instruction in same? (3) And if the material required to carry it on in a small way, say up to 12 x 10, size, expensive.—CROMWELL.

(1) "A Treatise on Photogravure," by Herbert Denison. (2) Photographic School, Regent Street Polytechnic, W., or the L. School of Photo-Engraving, 6, Bolt Court, Fleet Street, E.C. Apply to Penrose and Co., 109, Farringdon Road, E.C.

STUDIO.—Can you give me the most suitable alteration of these rooms for making an up-to-date studio, or can one be made out of the room A. The sides A and B cannot be fitted with windows as there are other shops on each side. Would you advise electric studio? Is it possible to obtain the same results as daylight?—J. H. B.

We cannot see from the sketch plan how it is possible to convert the two rooms into an "up-to-date" daylight studio. If you could increase the size of the south-east window, you would only get a studio seventeen feet long. If the electric light is available we should think the best thing to be done would be to throw the two rooms into one, and install the electric light. Very good portraits can then be done. When skilfully used, results are as good as those by daylight.

L.L., and Others.—In our next.

H. G. BUTLER.—"Photo Revue," 118, Rue d'Assas, Paris.

LINOLEUM FOR STUDIO.—I have built a studio, and should be glad if you would kindly tell me the best colour, or colours, for linoleum for the floor; very light, light, medium, or dark, etc., what would you recommend me? I have 9ft. by 8ft. top light and 9ft. by 6ft. side light. Thanking you in anticipation. JOSEPH GLOVER.

A linoleum of dark chocolate colour will be about the most suitable you can have for the purpose.

VIEWS AND NATIONS.—President Hadley, of Yale, and a young man whose appearance was that of a student, once met, says the "Searlight," in Yellowstone Park, in the midst of the wonders of nature. President Hadley turned to the young man for sympathetic comment. "This is a wonderful scene, isn't it?" he said. The young man smiled and nodded, and turned, without speaking, to gaze at the prospect spread before them. "Do you think," asked President Hadley, confirmed in his idea that he was talking to an ardent student, "that this chasm was caused by some great upheaval of nature, or is it the result of erosion or glacial action? What are your views?" "My views," said the stranger, quickly opening a bag containing photographs, "are only two dollars a dozen, and dirt cheap. Let me show you some."

•• NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

collection of portraits by Dührkoop will remain on view at the BRITISH JOURNAL offices until to-morrow week, May 26, after which it will be transferred to Liverpool, where the Liverpool Amateur Photographic Association will exhibit it in their rooms in Eberle Street from June 1 to 15. (P. 382.)

Photographic Convention of the United Kingdom. The arrangements for the Southampton meeting—July 9 to 14—are now complete. (P. 381.)

Lang Sims has been elected hon. treasurer and Mr. A. Mackie secretary of the Professional Photographers' Association, in succession to the late William Grove. Grievances of actors in regard to photographs were presented to the P.P.A. by a deputation from the Actors' Association. (P. 395.)

Questions of the right to publish portraits of celebrities have come before the law in the motion brought by Marie Corelli to restrain the issue of postcards of herself. (P. 383.)

A country reader of the B.J. offers free a photograph which has been usefully employed for advertisement purposes. (P. 397.)

Portraits for study by photographers at the Royal Academy. (P. 384.)

Instructions in scaling a spectroscopic camera are given by Mr. E. J. Wall. (P. 385.)

Researches as the alkaline constituent of tablet developers has been completed. The omission of the baryta coating in making gelatine emulsion papers is among other patents of the week. (P. 393.)

Prices of modern pictures have disclosed an extraordinary decline in the market value, one picture, previously sold at 480 guineas, being now only 6½ guineas. (P. 382.)

The autumn R.P.S. exhibition is announced for September 20 to October 27. The Salon opens on September 14 and closes October 27. (P. 381.)

An effort is being made to found a club in the West End of London on the lines of the old Camera Club. (P. 397.)

## EX CATHEDRA.

### The Photographic Convention.

The full book-programme of the forthcoming Convention at Southampton in July next has now been issued, and a very promising prospect it holds out for the week's meeting and excursions. We have announced the list of papers and visits in previous issues, so that it is not necessary for us to repeat information which may also be had for the asking from the secretary of the Convention, Mr. F. A. Bridge, East Lodge, Dalston Lane, London, N.E. We may say, however, that the reports which have appeared in the papers as to the work of restoration being carried out on Winchester Cathedral need not disquiet anyone who fears that on that account photographs of the structure will be defaced by scaffolding. The builders are at work on no part of the exterior, and inside the only portion to which their operations extend is the retro-choir, leaving a choice of architectural subject sufficient for many times the number of hours which the Convention can spend in the city. Of other features of the Convention it is surely unnecessary for us to speak. The conditions in Southampton are specially favourable to a highly successful meeting. The Philharmonic Hall, in the centre of the town, which is to be the headquarters, will accommodate both the meetings and the exhibitions of photographs and of apparatus, both of which latter, we are assured, will possess unusual interest for all classes of photographers. The yachting party "At Home" of the President, Mr. E. J. Humphery, on the Wednesday afternoon, should be one of many compelling functions of the Convention week.

\* \* \*

### The Autumn London Exhibitions.

The prospectuses of the R.P.S. Exhibition and of the Photographic Salon have now been issued, and are obtainable, the former from the Royal Photographic Society at Russell Square, London, W.C., and the latter from Mr. Reginald Craigie, Blenheim Club, St. James's Square, London, S.W. The Royal, we see, is to be run on very much the same lines as in previous years, except that a special section is to be provided for "an invitation collection of technical photographs and apparatus, not for competition," the character of which we believe is to be very similar to the competitive technical section. The Royal opens on Sept. 20, six days after the Salon, which again will hold its exhibition at 5a, Pall Mall East. This, year, so we are informed, foreign contributions will be submitted to a selection committee in London, instead of being selected by members of the Linked Ring in the country of origin. The effect of this reversion to a policy which has been broken only on the one occasion of last year, will probably be evident in the exhibition.

### Dührkoop in Liverpool.

The collection of photographs by Dührkoop now being shown at these offices until May 26 will be transferred to Liverpool, where they will be exhibited for a fortnight (June 1 to 16) by the Liverpool Amateur Photographic Association at their rooms in Eberle Street. It will be remembered that the Society, over which Dr. Thurstan Holland presides, and to which Mr. C. F. Inston has applied his powers of secretarial management, recently arranged for the exhibition in Liverpool of the chief portion of the photographs by Mr. A. L. Coburn, brought together under the auspices of the Royal Photographic Society. The work of Dührkoop should interest the Liverpool photographic public no less. Most probably it will be very much more to the mind of the body of photographic workers than the brilliant experiments of Coburn in landscape, though comparisons between the very different portraiture of the two workers will be difficult to make. It is anticipated that it will be possible for the collection of Herr Dührkoop's work to be seen in other provincial centres during the next exhibition season, either as a section in society shows or as a house exhibition arranged by local societies.

### Modern Physical Chemistry.

Last year we published some articles by Mr. Kenneth Mees on "Modern Chemistry for Photographic Workers," which dealt in a lucid fashion with some of the hypotheses of modern physical chemistry. Reference to these articles will show that the phenomena of osmosis and osmotic pressure are of fundamental importance, and that a most important assumption is that "the osmotic pressure of a substance in solution is the same thing as the pressure of a gas," to quote from Mr. Mees. From "Nature" for May 3 we now learn that Professor Louis Kahlenburg has arrived at some experimental results, that, if confirmed, must destroy the basis of the theory of electrolytic dissociation according to Arrhenius, upon which modern physical chemistry largely depends. From his experiments it appears that the osmotic pressure developed in the case of any solution depends essentially on the nature of the membrane used, as well as on the nature and concentration of the solution. There is no such thing as a definite pressure characterising a solution of given concentration. The pressure depends on the septum employed, and the results obtained do not agree with the gas laws. Fuller information is obtainable in the "Transactions of the Wisconsin Academy" (March) and in the "Journal of Physical Chemistry" (X., pp. 141, 209). The experiments, of course, have to be confirmed, but the results now given will not surprise those who have always held the opinion that many of the hypotheses of physical chemistry are based on a very unstable foundation. The phenomena of osmosis and osmotic pressure are very obscure, and, as yet, have admitted no analogy, and have not been explained in any reasonably satisfactory manner. Professor Kahlenburg's explanation to the effect that the result depends on the power of the membrane to "imbibe" the solvent and solute, and on the solubilities of the substances dealt with, seems, at first sight, to be as rational as the other theories that have been put forward. The collapse of the theory of electrolytic dissociation would not, perhaps, be of much moment to photographers, for physical chemistry does not seem to have brought us any nearer to the solution of the grand problem of the formation of the photographic image. But it is eminently desirable that Professor Kahlenburg's experiments should either be confirmed or disproved as soon as possible, for there is nothing so deceptive or so detrimental to progress as a false scientific "Theory."

### Control in Gum-Bichromate Printing.

The notes which appear elsewhere in this issue should mark a distinct advance in gum work. Hitherto it has always been advanced as a strong argument against this process by its opponents, and also as one of the strong points of its advantages by its adherents, that it was impossible to obtain two gum prints alike, and, further, the charm of the process lay in the fact that one never knew till the print was finished what would be the result. The possible explanation of these statements is that gum-bichromate has never been seriously attacked, at any time in England, from the scientific point of view. It was first exploited by the pictorial photographer, and at a time when the scientific principles, or the tools of the mechanic, were in bad repute. As it is nothing more than carbon printing, it is obvious that there must be certain rules and methods of working which should enable him who would to control his results, nor does it seem feasible to suggest that what is obtained once cannot be absolutely duplicated under similar conditions, when a sensitive film of constant composition printed under given conditions is used. Considering that now some of the more extravagant claims and extraordinary results by this process are discounted, and in the face of the fact, noted in our issue for April 20, that direct enlargements can be made on gum-bichromate paper, we ought to hear a little more of the general use of this process.

\* \* \*

### A Slump in Modern Pictures.

On more than one occasion, during the past year or so, we have alluded to the high, indeed, almost fabulous, prices of paintings by old masters have realised at auction sales. While the value of old pictures seems to be increasing, that of modern ones, of the Academy type, appears to be decreasing to an amazing extent. At Christie's, one last week, some pictures by R.A.s were sold, and at the same time the following:—W. P. Frith's "Pope and Lady Mary Montague," which in 1875 sold for 1,350 gs., in 1881 for 1,190 gs., made but 460 gs. F. Goodhall's well-known picture "Raising the May-pole," which in 1875 made 1,470 gs., was sold for 400 gs. Egg's "Peppercorn Nell Gwynne," that once made 1,200 gs., fetched 150 gs. Elmore's "Columbus at Porto Dante," that in 1879 made 480 gs., was knocked down for the small sum of 6½ gs. The auction room is always a good index of the existing state of the picture market for certain classes of pictures. At the present time it would seem that the pictures by old masters are at a premium, while those by modern ones are at a very considerable discount.

### Sartorial Art and the Royal Academy.

Our good friend the "Tailor and Cutter" is always highly amusing in his comments on the pictures shown at the Academy. This time it is his severe opinion of the painters of portraits—for example, it is his "is evident that the present generation of painters—can't call them artists—are incapable of seeing the details of clothing, and the consequence is they utterly fail to produce any art that will last." Also, "If this kind of painting continues, we shall have to get the artists to put tickets on the various parts, and say 'This is intended for a coat'; 'This is a waistcoat'; 'By this we wish to suggest trousers'; otherwise it will be impossible to tell what it is intended to convey to the mind of the person looking at it." Our contemporary is equally caustic in his comments upon other details of clothing as represented at the Academy; but it might save some of its criticism for a plate which appears in its own pages. This, it is

supposed, is consistent with the "Tailor and Cutter's" of what pictures should be. It represents a standing figure the length of which is something like ten times that of the head. The legs are posed apart at about the same angle as that of a pair of house painter's trestles when in use. The trousers show no indication of ever having been formed to a sitting position of the wearer's legs; they are as straight and unpuckered as one sees them displayed in clothiers' windows. The boots would seem to be odd sizes, and the walking stick is used with the left hand. It is possible that if artists were to get this "picture" and carefully (?) pose, and paint, their portraits according to the way they would avoid the annual strictures of our contemporary.

**Process Situations in Paris.** Several advertisements having recently appeared in the London papers offering sittings in Paris to process photo-engravers, we may suppose that the cause is a strike or lock-out there, and therefore inquiries should be made before any situation is accepted, not that we suppose that photo-engravers will be treated as were the English labourers who went to Hamburg to fill the place of the dockers on strike there—but it is, thrown into the water. Nevertheless, it is certain that English workmen would seriously resent their places being filled by Frenchmen in the case of a trade dispute, and so they will probably not care to give rise themselves to similar resentment in France.

**Marie Corelli and her portraits.** A case of considerable interest with regard to the right to publish portraits of persons against their wish has been, and is, before the Law Courts. It is *Corelli v. A. and E. Miss Marie Corelli*, the plaintiff, we understand, has made a great objection to any portraits of herself being published. The defendants, some time ago, published portraits of the lady, made from drawings, purporting to depict scenes from the private or home life of the plaintiff at Stratford-on-Avon. These were sold at the shops in the neighbourhood. On complaints being made most of the sellers withdrew them from sale, but the defendants, by means of sandwich men, advertised that they could still obtain them at their establishment, whereupon the plaintiff consulted her solicitor, who commenced legal proceedings, it being alleged that the pictures were libellous, and an interim injunction was granted by Mr. Justice Lawrence, vacation judge. A little while ago an application was made in the Chancery Court, before Mr. Justice Swinfen, to continue this until the trial of action. After arguments, *pro* and *con*, the judge reserved judgment, but on Thursday last week declared that the question he had to consider was whether the plaintiff had made out such a case of legal inquiry as required the Court to interfere at the stage of the action. He was not satisfied that the pictures were libellous, and, in any event, the case was not so strong as to justify the Court in interfering before the question of the libel had been established. He further said that it was urged that the plaintiff, as a private person, was entitled to restrain the publication of portraits of herself which had been made without her authority, and which, though professing to be her portrait, were totally unlike her, but she had not established that she had any such right, and under these circumstances he did not see his duty to grant an interlocutory injunction; saying, further, that if the plaintiff should at the trial establish that the pictures constituted a libel, she would have her remedy in damages against all vendors, and the only order he could make was that the costs of the motion be costs in the action. The matter rests for the present, and no comments can

be made upon it, but we look forward with interest to the result of the trial, if it comes off. Many of the daily and weekly papers habitually publish portraits of persons appearing in the different Courts—from sketches made in Court—as plaintiffs, defendants, or witnesses, often to their annoyance, but we are not aware that any legal action has been taken by them, although many are anything but complimentary.

**Photographing Buildings in Crowded Places.** One of the difficulties confronting the architectural photographer in busy thoroughfares is the constant passing and repassing of pedestrians. Where the number of people is great, as, for instance, in such main arteries of traffic as Fleet Street or Holborn, or similar thoroughfares in the large provincial cities, it is only possible to do satisfactory work in the very early morning, and even then passers-by may make the work somewhat difficult. The landscape worker's method, employed in gusty weather—that of using an everset shutter and giving an exposure in sections between the puffs of wind—may sometimes be adopted. It is, in fact, often used in interior photography in such frequented buildings as the Oxford College chapels, Westminster Abbey, and so on. Another method which we have seen used successfully is to use a very small stop in the lens and to make the negatives on slow plates. A slower plate than that described as "ordinary" may be used, such, for instance, as a lantern plate, or, better, a photo-mechanical brand. Such a plate will require, roughly, ten times the exposure which would be necessary with an "ordinary," and the prolonged exposure allows figures to pass and repass without a trace of their presence being visible on the developed negative. It is not well to use a smaller stop than  $f/44$ , as there is a risk of the definition being impaired owing to diffraction. In developing slow plates of the kind suggested care must be taken to prevent the production of too hard a negative. As a rule, photographs of the class of subject we are referring to need to be bright and plucky, but to avoid excessive contrast the usual developer may well be diluted with an equal bulk of water.

**Printing Inks in Fugitive Colours.** We were recently shown a "three-colour-work" print that had formed a supplement to one of the leading art magazines. This print, representing the figure of a girl whose locks and primitive costume were blown about by the wind, was a choicely-coloured piece of work—at least, it was so originally. But its admiring owner had framed and hung it upon a wall by no means brilliantly lit, to the right of windows of a N.E. aspect. Direct sunlight was impossible to it; yet in the course of about two years all the red had entirely faded out, so that the maiden, formerly in the glory of auburn tresses and a warmth of healthy youth, had become a grey-haired corpse erect in a cold and forbidding landscape. We doubt whether it is to the ulterior interests of printers and publishers, and the enduring reputation of three-colour work—to say nothing of the business ethics of the matter—that fugitive lakes should be used in printing inks for this kind of work. They have long since been eliminated from the palettes of painters worthy of the name; and only the schoolboy now plies his crimson lake rather than rose madder. Our printers would seem to be in the position of the schoolboy: they do not care to buy the more expensive but permanent madders when the cheaper aniline, Campeachy wood, or cochineal products answer the purpose for the moment. If three-colour work is to be the photographic event of this decade, it is hard that it should be discounted by pennywise principles.

## THE ROYAL ACADEMY.

IN view of the many and various "supplements" of the weekly magazines comprised of reproductions of Academy pictures—considering also the volumes that are devoted to nothing else but these reproductions—it becomes a matter of no moment whatever that this journal leaves such luxuries to others. An article upon the pictures may, nevertheless, be the better understood by a glance at these ubiquitous illustrated sheets, and therefore it is taken in hand with something of the comfortable reassurance that accrues to the demonstrator from his diagrams and statistical curves.

For a year or two yet, perhaps, it will be but heaping coals of fire upon the heads of photographers to comment upon the first charm of painted pictures—that is, their colour. It will be different when we are able to give our coloured supplements—very different for the "gate" of the R.A., and very much better for us than the head-aching function which the annual shillingsworth involves. For the present, however, we must not waste space upon colour comments. The photographer, being a practical man, except when his "temperament" is troubling him, will read an article about pictures chiefly in the hope of picking up an unconsidered trifle in the shape of a "tip" or a "wrinkle." Many of such tips and wrinkles may take the shape of warnings. For instance, A. C. Colthurst's picture of a wake, "Watching the Dead in Ireland," has a subject distinctly to be avoided. No amount of cleverness could make it fit for anything but a sedative to over-hilarity of mood. Another unfortunate choice is exemplified in the life-sized portrait of a motor-car, which naturally covers a deal of valuable space that might have been devoted to things more interesting and less well-known. True, the Hon. Mr. and Mrs. Douglas Carnegie, with their sons, John and David, appear also, but only as accessories, more or less suppressed by the artist.

By authority, if not entirely by conviction, we are persuaded to regard John S. Sargent, R.A., as our finest portrait painter. He is represented by four portraits and a landscape, and, to our shame and sorrow be it said, we find no mark of admiration against any one of them in our catalogue. His portrait of Lord Roberts is a very satisfying thing, as presentation portraits should be, showing the little hero with every inch of war paint crowded on. But the clever part is that the hero looks not little, but big, and that without any violation of proportion. He is represented as ascending the stairs of a palatial building in such a way that his lower limbs are partly hidden. This plan leaves their extension possible to the imagination. The likeness is excellent, no doubt; but the sitter has the look of having very recently left an over-heated bath. It may be that Lord Roberts's complexion is not falsified in this respect; but of one thing we are quite sure, that a coat-sleeve of the complete gentleman should appear to have an arm inside it; and that a chest, even when at bursting point with military ardour, should not look like that of a pouter pigeon stuffed by an over-zealous taxidermist. Another important work by Mr. Sargent is a presentation group of four Professors of the John Hopkins University, Baltimore. It strikes the photographic critic that, with all the past in art easy of access to Mr. Sargent, that painter might to some purpose have given a glance at groups by the old Netherlandish masters. His heads are as so many lanterns in a dark place. Only in one case has a quieting shade been allowed to modify their aggressiveness. This occurs with the standing figure behind the table. The three seated figures, though at points varying in distance from the point of sight, are

each practically of the same scale, the same height, tone, and the same staring posiness. The deliberate adoption of unnecessary conventions, and the wilful feigning of each portrait for its own or its sitter's sake, in our humble opinion, caused Mr. Sargent to waste a fine opportunity.

Background styles seem as variable as ever. "Pillar and Curtain" is still with us, but, as employed by Mr. Harris-Brown in his "Lord De Ros," and in Enderby's "Highland Gentleman," these time-honoured materials are made too massive and monumental to carry conviction. The plain background is apt to run to sloppiness or a thin scribbledness, and thus not be properly tiring. On the whole, it would appear that painters like Sir George Reid and Mr. Solomon, preserve a happy mean between still life and sloppy suggestion in a necessary details of furniture get the best results. The latter's "Lilian Ruth" is delightfully easy in pose. "Sir Aston Webb, R.A.," however, is a little too vivacious. One almost expects the subject to spring up out of his chair. A more decorous virility is seen in Professor V. Herkomer's "Sir Felix Semon." He looks as an animated conversationalist would look when self-contained enough to keep his hands in his trousers pockets. As customary with this painter, the figure is cut off just below the knees. "Mrs. Leopold Albu," by the same artist, is so happily placed on the canvas. She has a slipped-dress look, due to the empty space left above her head.

A group of great charm is J. J. Shannon's "Mrs. Sears and her Daughter." It may be highly recommended as a model in posing. And so may Mr. Bacon's group of children, which he calls "A Fairy Tale." These three little girls sprawl upon a sofa with the true negligence of youth, whilst one of them reads aloud. Mr. Cope seldom if ever, disappoints. His work is always sound and satisfying. Although a presentation portrait, his "Marquis of Bristol" is quiet and dignified by its absence of state fuss and paraphernalia. The painting of the head and hands could scarcely be better, and the manner in which their height and tone is massed together by the grey of the waistcoat that connects them is thoughtfully artistic. The Lord Provost of Glasgow is shown in a pose that is "fine" and expansive, whilst it is perfectly easy and free from bombast.

Mr. Frank Dicksee's "Duchess of Westminster" has not been highly praised by critics, though the public will not doubt give it all the admiration it deserves. Its ample silk robes of pink seem to have offended, and certainly shadow over the lower part of them would have been welcome. But no one can deny the nobility of the whole design, and for skill of execution it is not easy to beat. The figure is, at any rate, supported by a living skeleton beneath the robes, and the beauty of the form is gracefully given.

Although Mr. Salisbury is yet a young man, his "Amy" makes one think of Reynolds. It has great distinction of style. The face is a beautiful one beautifully rendered, and in posing, lighting, and general harmony of tone and colour holds its own in the galleries. In the water-colour room are two life-sized portraits that deserve a word. One is a *tour de force* by Byam Shaw, representing, at life size, a judge's daughter robed in blue of a hard tint, and walking in a brown landscape that occupies five times the superficial area of the figure; the other is a simple and unambitious portrait by Miss Gow, of "Miss Edith Gow," the nobility and grace of which draws one's sympathies; whilst the dash and cleverness of the other leaves them unmoved.

The landscapes at the Academy are of far greater interest and merit as a whole than are the portraits—that is to any but the camera portraitist. But of those works the present space forbids us to speak.

## THE USE OF THE SPECTROSCOPE.

IV.\*

There is one point in connection with the lines which is sometimes confusing to a beginner that possibly I should have mentioned before. We are accustomed to talk of C, F, G, and little H as the hydrogen lines, but it is very usual to call these all H lines, and distinguish by the small letters of the Greek alphabet:  $H_\alpha$ ,  $H_\beta$ ,  $H_\gamma$ ,  $H_\delta$ . As we have the two  $H_1$ ,  $H_2$  Fraunhofer lines, it may possibly give rise to confusion.

### The Camera Scale.

In making the scale for the camera, the easiest plan is to purchase a millimetre scale ruled on glass, and fix just in front of the slit aperture in the back of the camera. Mr. A. J. Newton gives an excellent method in "Penrose's Annual,"

platinum wire. If a good, roaring bunsen burner is available it is quite sufficient to jam a piece of fine brass gauge down the tube, sprinkle some of the salt on it, and then turn on the gas and light up; if the salt is finely powdered small particles are carried up into the flame, and we get the characteristic line.

There is a convenient little apparatus known as Mitscherlich's, which is practically a series of test tubes inverted, with the open mouth bent round at an angle, and drawn to a capillary point, in which a bundle of platinum wires is inserted. The solutions can only be forced into these tubes by atmospheric pressure; but that is very easy, because the closed end of the tube is heated and the air driven out, and then the capillary

Fig. 1.—Ordinary Plate.

1905-6, p. 81. The method I adopted was to copy in the camera a 12in. ivory rule divided into  $\frac{1}{16}$ ths of an inch. This I happened to have, but good boxwood metre and half-metre rules can be obtained, which can be easily photographed down to the required size, and, with the usual precautions, the divisions and figures will be as clear and as distinct as possible. Mr. Newton takes five copies on one plate, so that each spectra is accompanied by a scale; I merely use the scale for one spectrum, and then, with a needle-point, rule straight lines down the plate through the others corresponding, of course, to the Fraunhofer lines. The positive with the scale is cemented into the dark slide.

Any bunsen burner can be used to obtain the lines of the chlorides that we propose to use; and Tallent suggests using

Welsbach burner, with a wire inserted in the central hole that usually takes the fork, this wire terminating in a flat spiral, which is covered with asbestos. Any arrangement that suggests itself can be used; my arrangement was a loose bundle of asbestos, about the thickness of a lead pencil, bound with

Fig. 2.—Orthoplate.

end inserted in the solution; then, as the heated air contracts, it naturally sucks up the solution. My experience with this was not so satisfactory as it might have been, as, notwithstanding the use of ammonium acetate solution as a solvent, I found the liquid loth to run down the platinum wicks, and the light was inconstant.

### Plotting Spectrum Lines.

It is essential, of course, to use a panchromatic plate to obtain all the lines, and colour-filters are also necessary. These latter may or may not be ordinary three-colour filters; coloured glass is quite as effectual. Assuming that everyone has a copy of the "Almanac" for 1906, on p. 1,109 will be found a table of the salts and lines that they give. In the first place it is advisable to make saturated solutions of the salts in distilled water. Then, having set the bunsen burning, and seen that the spectrum is fairly brilliant all through—which can be easily done by temporarily stopping up with the fingers the air hole at the bottom of the tube—and the slit level with the top of the bunsen blue flame, we can insert our dark slide, place an orange screen in front of the slit, and proceed to photograph the two lithium lines at 670 and 610. The duration of exposure will

\* This article is the concluding one of the series. The preceding papers appeared on April 20, May 4, and May 11.

naturally depend upon the brilliancy of the light and the sensitiveness of the plate to this region; with a commercial panchromatic plate it may vary from five to ten minutes—probably, with a pinachrome plate, it would be much less.

For the sodium, or D lines, either the same filter may be used or one of a lighter colour; it does not matter much, for the sole purpose of the filter is to cut down the faint continuous spectrum which is always seen; the exposure may be reduced in this case, as a rule, to five minutes. Naturally, after each exposure the dark slide or the spectroscope is shifted so that each metallic line or lines has a spectrum devoted to itself.

Magnesium ribbon will give us little *b*, or 518; half an inch is plenty, as a rule, with a green filter. The only important point to note about this is that  $\lambda$  518 is the extreme edge of the line towards the red. The trouble with the magnesium flame spectrum is that one not only gets the lines due to the metal, but the broad bands due to the glowing MgO, and therefore we can easily make a mistake between 518 due to the metal and 490 due to the glowing oxide, but the shorter the exposure the less the latter shows itself; besides, one can always check the result visually by the solar spectrum, because little *b* is one of the most prominent lines in the spectrum—far more so than E.

Strontium chloride gives us 460, calcium chloride 422, and potassium 408. All these should be taken without a filter, and the exposure in each case need only be about a minute. Now, unless we split the spectrum in one or more cases, it is obvious that we cannot obtain all these spectra on one plate, so that one must either cover half the slit for one of the spectra, or else obtain two of the fiducial lines in one spectrum. If this method is adopted the most convenient are certainly the D and the blue K or potassium at 404, as the former can easily be obtained as described above with an orange screen and the latter with a violet screen, and they are sufficiently far apart and distinct to lead to no trouble. We might use strontium and calcium, but as they are both extremely rich in lines in the orange and blue, one might confuse the reading for D or mistake one of the blue lines.

#### Spark Spectra.

As regards the use of the induction-coil, as already stated this is extremely useful with a hydrogen tube, but as the whole of the fiducial lines may be obtained with a Collie compound tube, this is preferable. Naturally, the cost is more, for, as already stated, helium is one of the contents, and this is always expensive; but it will be seen from the following data that the distribution of lines is fairly even:—Helium, red, 706; helium, red, 667; hydrogen, red, 656; mercury, orange, 615; helium, yellow, 587; mercury, yellow, 579; mercury, yellow, 576; mercury, green, 546; helium, green, 501; helium, green, 492; hydrogen, blue, 486; helium, blue, 471; helium, violet, 447; mercury, violet, 435; hydrogen, violet, 434.

Of course, one may use magnesium rods with the coil, then 518 becomes very faint; there is practically no continuous spectrum, and 448 becomes very strong. The real trouble is that the spark spectra differ according to the particular conditions, especially as regards density; for instance, if one uses two magnesium poles, the spectrum is different to that obtained

with one magnesium and one platinum pole—different, that is, in intensity of the lines, with the result that the beginner gets in a fog.

Precisely the same argument applies to the use of the arc and carbon poles. When one can obtain absolutely pure carbon rods, and when one knows all the carbon lines, then, of course, scaling is easy; but, as it is possible to treat carbon rods for forty-eight hours with various chemicals to remove stray metals, and then use them with satisfactory results for a short time, and then gradually see one or other or both of the Ca lines appear, one begins to have doubts as to the removal of the other elements, and therefore hesitates to accept this method for fiducial lines.

Having, however, obtained the lines on the negatives with the various salts, the preparation of a chart and the interpolation of other lines can be proceeded with exactly on the lines laid down in the "Almanac."

#### Testing Plates and Filters

As regards the testing of plates, the best way is to fix on some minimum exposure—one that will give a faint impression, then give increasing exposures with succeeding spectra. As an example, possibly the two accompanying illustrations may explain the procedure which have been made this last week in a Tallent spectroscopic camera that I was asked to scale. No. 1 shows the spectrum on a rapid plate, with 1, 5, 10, 20, and 40 seconds' exposure to a Welsbach, and No. 2, absolutely the same exposures on the same emulsion sensitised by the addition of certain dyes. Although the light source is rich in yellow rays, there is no question about the value of the dyes as sensitisers, for, roughly, the scale is O = H, G = 13, F = 26.5, E = 33, and D = 40, and the additional sensitiveness beyond F is very clearly shown with the dyes, although there is still just a slight drop in the shorter exposures in the usual position so characteristic of the eosine group.

The question of illuminant is a trouble, for unless one adopts the Mees and Sheppard screened acetylene light, one must fall back on the Welsbach, and the sensitiveness to this is quite wrong, when compared with daylight, which one cannot use because of its variability. A negative such as the above, however, proves the initial fact that a dye or mixture of dyes is of value in sensitising, and then the action can be checked by photographing a chart of colours of known luminosity.

Precisely the same trouble is met with in adjusting a yellow screen with the spectroscope and an artificial illuminant, unless one knows the ratio of yellow to blue, and has a photometer to read the negatives, but with a chart the results of the former can be easily checked. When it comes to the making of three-colour screens and defining their absorptions it is much easier, for one has not to deal with ratios, but definite absorptions.

The above notes are purely elementary, but may possibly be of service to some. To the more advanced worker "An Introduction to the Study of Spectrum Analysis," by Watts, may be useful, but to the spectroscopist who wishes to utilise photography, then "Spectroscopy," by E. C. C. Baly, and Eder and Valenta's "Beiträge zur Photochemie und Spectralanalyse," are quite indispensable.

E. J. WALL, F.R.P.S.

THE Antwerp Municipality, according to a Glasgow paper, now delivers free passes to professional or amateur photographers for use whenever the circulation of the general public has to be restricted, on the condition that they undertake to give two copies of every snapshot taken.

At the Royal Institution of Great Britain, on May 11, Mr. Oliver Dawson gave demonstrations of the Dischner process of natural backgrounds in studio portraits, described in our issue of May 4, and of the printing-out process in natural colours on paper, invented by Drs. J. H. Smith and Merckens, reported by us in our issue of April 27

last. Both the processes attracted a good deal of attention, but as the large assembly embraced many amateur photographers, the latter process, which puts into their hands the making of coloured prints from their own negatives, created, perhaps, the greater interest. The demonstrator pointed out that this P.O.P. paper solves the latter half of the problem of photography in colour—viz., the making of the prints. In reference to the offer of free samples of this paper, we are asked to say that the stock has been quickly exhausted, but Mr. Dawson, whose address is 254a, High Holborn, hopes soon to be in the position to meet all demands.

## AMERICAN PHOTOGRAPHERS IN CONFERENCE.

The following is the discussion of others of the twenty-three questions set down on the agenda of the Convention of the Professional Photographers' Society of New York. Not all the topics, of which it will be remembered we printed the list in our issue of March 30, proved suitable for discussion, in some cases the lateness of the hour debarring the ventilation of a subject which might, at an earlier stage in the proceedings, have prompted a profitable discussion. However, the comments of the members of the New York P.S. can hardly avoid being helpful to readers in this country, as showing the point of view from which the American professional looks at many of the problems which beset him. To the account of the concluding discussion, which we reprint from the official columns of the "Photographer," we add one or two comments by readers of that newspaper. We propose to quote any further letters or communications which may appear in the American Press as the outcome of the recent "business" Convention.

### THE PHOTOGRAPHERS' ASSOCIATION OF AMERICA.

Can the P.A. of America be made of real and practical benefit to Photography?

Mr. Macdonald: I should like to call on and introduce to you President of the Photographers' Association of America, Mr. Hearn, of Boston.

Mr. Hearn: Ladies and Gentlemen: I didn't have in mind until this morning about five minutes that I was to be expected to speak to you today. I had an idea that I might possibly be called upon at the other end of the hall, where ladies would not be present before us, and then I would face the music much better. Now, in regard to how can the Photographers' Association be of benefit, I would say that we are at the present time, the Executive Board, to the Professional Photographers' Society of New York, inasmuch as we have set up a room in Niagara Falls for your headquarters, where you can meet and where you can make your appointments, and where you can stay at home. Coming upon your soil as we are, we feel it incumbent upon us to establish a precedent which has never been established in the national body before, to give recognition to the photographers of that section to whom we go. I think it is a very nice thing that Mr. Hoyt suggested this to us, and its feasibility at once became apparent to us. Consequently, if you come to Niagara, as I hope you will, you will find a little room for your own, as you have here. As to the question of dealing with your customers, the youngest could bear in mind that you represent a new art, the youngest of the arts, and you should always bear in mind that you want to be that art high up. We all grow and we all advance simply upon the fact whether or not we make good along certain lines. If you put photography to stand at the top, then be men of integrity and honour. Don't try to get the best of your fellow-man, but try to deal with him as you would have him deal with you. We will probably not have the exhibition such as you have on the walls, but we will try to see if we cannot, by the engagement of speakers and people who are able and competent to talk to you, we will see if we cannot do something for your good, something that will be of practical value. I was talking with a friend of mine within the past twenty-eight hours, and asked him how much money he made out of his gross business of one year of \$5,900. He had the figures right hand, to my astonishment, and he told me he made \$2,700. Now

that gives a very good idea of what can be done on a small, moderate amount of business, and it is not a question, gentlemen, of how to get a bigger business, whether it is best always to advertise in the newspapers or in the theatre programme, or whether you will do that thing or the other more or less legitimate, and some possibly not so, as whether or not it is better to conserve that business which you have on hand. We must build up a certain line of customers who will come to us and patronise us at all times if we treat them right. Now, the right thing to do is to make the most out of that business we have. The gentleman who said he was in business for the money he could get out of it did not mean that exactly. Whatever we have to do in photography we have something to do because we love it. We can love our business, and at the same time we can conserve it and make it pay us well. Now, we will try to do that and show you how it can be done. Now, how can we do large things in our business? Whether small or large, there are a great many avenues in it; the employment of time, which is a tremendously big factor, and also making the most of the opportunities that are with you. We can all look back upon years when we have done things not profitable to ourselves, and we have got the advantage of experience. Your efforts should be directed to one end, how to make the best of the business that you have. There is in this room a young man. He came to me two years ago, perhaps a little less, and wanted me to take him into my place and teach him photography. I turned him down, I didn't want him. He kept persisting to do that. He told me he was willing to make sacrifices in order to do it. I said, "Can you afford to do that?" He says, "I have got \$50 saved up. I shall live economically and I shall make that \$50 go as far as I can to make the first step in it, and I will make \$50 more." He was very ambitious, so very ambitious that it got tiresome at times; but still I admired his pluck and his energy. He has kept persistently at it, and he has spent something to come to the Professional Photographers' Society of New York, for the sake of learning what he can learn. Gentlemen, that is just exactly what we want to do if we want to advance our art and our business. We want to give all possible encouragement to young men who really mean business.

### THE PHOTOGRAPHIC PRESS.

How Can the Photographic Magazines be Made More Interesting to the Professional Photographer?

Mr. Hearn: I want to tell you what a magazine can do to be of advantage and of interest to photographers. If the editors of our magazines can drop a great deal of this talk in regard to different considerations and get closer to what a photographer really wants, it will be better.

Mr. Abel: Mr. Hearn says something about the editors of photographic magazines getting a little closer to the professional photographers. That is not so much the point as the professional photographers themselves getting in touch with the editors. I think we as much as possible to keep in touch with photographers and communications and by letters, or in one way or another get up an acquaintance. But we seldom or never get any response from the individual photographer. We ask him to let us hear from him, by word or picture, or anything else, and hardly ever do we get any response. They do not really let us know whether they are alive, and as a rule they do not care to buy or read the photographic magazine at all. It may be that it does not appeal to him. We are willing to concede that, but even when we do get him to take the paper he does it as

a sort of concession to the editors. Now that is not the way to look at it, and I think if some of the gentlemen present here who do read some of them would get up and say why others generally do not read the photographic magazines, and what the editors should do, we could then see if we could not make an interesting magazine for the professional man to read.

Mr. Macdonald: It really does seem as though there was an opportunity right now of having given to you exactly what you want. (The attitude of the editor, as expressed by Mr. Abel, is, in my opinion, unquestionably the attitude that they really do assume. I am sure that they would be glad to give you what you want if you would only tell them what you want.)

Mr. Rockwood: I am afraid that Mr. Abel has put some of us young fellows in the wrong by saying that we do not appreciate the photographic magazines. I have been in business only about fifty years, and I assure you that from the first day that I have gone into it I have subscribed for almost every photographic magazine published in this country, and almost always two from the other side.

The result is that I have been, I believe, up to date in almost everything that was going on, and I will say this of the magazine that this gentleman represents, that many and many a time I picked up one magazine—one copy—and got out of it far more than the year's subscription. I will say that, in justice to Mr. Abel and the admirable magazine he is putting out, there is one series of articles going through there now that I don't know where else we could obtain them, and it has excited the enthusiasm of myself and my people to try some experiments just on that line. It has been my hobby to have what I call the library, and a copy of the magazines is placed there every month, because it is only lately that we have had a weekly magazine, for the general benefit of our employees. Now, if you can scare up a better set of employees than I have got, I would like to know it. One man has been with me thirty-nine years; two, thirty-six years; and one, who is sitting behind me here, twenty-five years. They have not only my assistance, but the assistance of all that comes out of good magazines and books. Men have asked me in this room things that I was amazed at, things they ought to know. I was very glad to answer the questions, but they would

not have been obliged to ask those questions if they took any of the admirable magazines that are being published now.

Mr. Parkinson: There is a great deal in the magazine that does not amount to much. Perhaps there are articles on chemicals; you are not interested in that line; there are articles on developers you are not interested in. Yet what a small price the magazine costs! I take the newspapers every day, and I do not, perhaps, read more than a few headlines in them. If I had those papers by the year I perhaps would not take them. I am a very poor reader of magazines in the way of reading the dry articles, but the little things, the little thoughts—why, even Abel has thoughts sometimes. If that weekly—"The Photographer"—fifty-two times a year, remember—if that weekly was brought to your door every week, once a week, if some body said to you, "Take this for four cents." you would pay four cents every time. But if you paid two dollars when the year was up it would cost you exactly as much. A man thinks that it does not cost him as much when he pays a little at a time. As I say every photographer in the United States would take "The Photographer" if they could take it that way.

### TICKET SWINDLERS AND LEGITIMATE PHOTOGRAPHERS.

William Henry Langdon writes: "In reference to the first question, How can the ticket swindlers best be discouraged?—my opinion is that the P.P.S. of New York act as a body of the whole to get every photographer in the State, member or not, to join and sign a statement that they will refrain from selling tickets on any reduced plan in their respective locality; that the president draw up an agreement to this effect and send same to each section secretary, who, at their local meeting, will appoint a committee to call on all photographers in its section and have it signed, sending the contracts to P.P.S. of New York. The names should be brought up and read at our next convention, and also be published in our photographic journals, so that we may all know who and what fellow-ships we are coming in contact with as honest photographers."

E. G. Merrill writes: "The photographer is certainly arriving to the dignity of a professional man, as he can show that he can hold a convention without someone else paying his bills; an elevated position I sincerely hope the P.A. of A. and the P.A. of N.E. will sometime attain. The New York State Society is ideal and magnificent, competent to formulate a code of ethics, worthy of the adoption of every society in our country, and a man living up to such a code would come pretty near being a 'legitimate portrait photographer.' On the other hand, a man issuing tickets in any other manner than the ones prescribed in the code would be guilty of a misdemeanor and unworthy the affiliation of the aforesaid 'l. p. p.' This is my suggestion of how to discourage the ticket swindler."

## SOME NOTES ON THE GUM PROCESS.

THE following notes are briefly abstracted from Dr. Köster's work, "Der Gummidruck," published by Knapp, of Halle, to which reference was made in our issue for April 20. They are interesting in that they throw a little light on the effects obtainable by varying the modes of preparation and development, points which, so far as we are aware, have not been touched upon by English writers, or, if so, only in a perfunctory manner. The information given is of such a nature as to make it possible to produce more than one single impression of given character from a negative.

To prepare the sensitive coating three solutions are necessary:—

#### The Gum Solution.

or	Gum arabic .....	60 parts.
	Water .....	100 parts.
	Gum .....	60 parts.
	Sugar .....	20 parts.
	Water .....	100 parts.

The latter is rather more fluid and makes development easier than the former.

#### The Bichromate Solution.

(a)	Potassium bichromate .....	10 parts.
(b)	or Ammonium bichromate .....	40 parts.
(c)	or Sodium bichromate .....	190 parts.
	Water .....	100 parts.

It must be noted that in this and the gum solution the quantity of water is not "to 100," but 100 parts. Practically equal volumes of the above solutions give varying sensitiveness—that is to say, 1oz. of (c) used instead of 1oz. of (a) will increase the sensitiveness thirty times over (a), whilst (b) gives an increase of ten times over (a).

The special colours recommended are Günther-Wagner's, and Winsor and Newton's cake colours, and one part of the colour should be ground up with ten parts of water.

As regards the paper, almost any sort may be used, but it should be free from wood fibre, and those specially mentioned are Schleicher and Schüll's roll-drawing papers No. 751, 759, 763, 764, and 765 and sheet drawing paper 109, 143, 144, 145; Schmincke and Co.'s 31; the rough hand-made papers of Zander's 1d, 1e, 1g, and the machine papers 792, 802, 812, and Schöll's "German Whatman," with the watermark of a hammer.

All the above papers do not require sizing unless special effects are desired. If a paper requires sizing, then a 2 to 10 per cent. solution of gelatine should be used with 2 to 10 per cent. of a 5 per cent. solution of chrome alum. The paper may be immersed in this for ten or fifteen minutes or painted over. As a rule a 2 per cent. solution will be enough.

As regards the composition of the sensitive mixture, the important point is that it shall give pure whites in the unexposed parts by development in cold water, and this depends on the proportion of gum to colour and on the sizing of the paper. The way to test this is very simple. If a plain water-colour be painted on a paper and then dried and immersed in water, very little colour will be removed, but if increasing quantities of gum are added, a point will be reached when it will completely dissolve and leave the paper quite white.

#### Adjusting the Coating Mixture to the Pigments.

To one part of the 10 per cent. solution of colour should be added half-part of gum solution, and seven such solutions should be thus made, each containing an extra half-part of gum. If, now, a little of each solution be painted on the paper and dried, and then the paper floated on the surface of cold water for about half an hour and occasionally moved and examined, it will be found that a particular mixture will completely dissolve and leave no colour, fog, or tint. If the paper is sprayed or the rose-tap used, then another mixture, with greater proportion of gum, will completely dissolve.

t mixture which dissolves by merely lying on water is called "normal gum," and this varies with each colour.

The proportion of bichromate salt has no influence on the gradation.

The following is an example of an actual sensitiser:—

Gum solution .....	3 parts.
Lamp black solution, 1:10 .....	1 part.
Potassium bichromate solution .....	2.4 parts.

Normal requires the same quantity of gum, burnt sienna 2 parts, Prussian blue and burnt ochre  $3\frac{1}{2}$ , and vermilion  $2\frac{1}{2}$  parts of gum solution.

Thin coatings give softness, and thicker coatings increased contrast, but the number of gradations are practically the same.

### "Normal" Development.

The author divides development into two kinds—one which we call "normal" and the other "mechanical"—though these are not his terms. The first is effected by immersing the print downwards in cold water and allowing it to remain so—with occasional lifting, for examination, to see how development is proceeding—for about an hour. All the gum that has not been rendered insoluble by the action of light will thus dissolve without supplementary assistance.

When the print is finished in less than an hour it may be assumed to be under-exposed. If it is over-exposed the image appears very flat, and if at the end of an hour only the highest lights are visible, it is advisable to have recourse to the second process of development, which is by the aid of a rose, sawdust, brush, or

any of the very few degrees difference in the temperature of the water tends to alter the time of development considerably, and with very warm water, development may be completed in a quarter of an hour; with cold water, it is so much lightened by this method that it must be used for a much longer time, and it is questionable whether the image is not removed from the paper and distortion of the same introduced, which is a disadvantage for combination printing. If, instead of a weak solution of potassium carbonate be used, then this method gives even the most exposed parts of the print; its use will give flat prints.

### "Mechanical" Development.

Mechanical development with a rose or stream of water, sawdust, brush necessitates printing one or two actinometer degrees more for normal development. It is advisable to immerse the print in cold water till thoroughly wet, place face up on a sheet of glass, then proceed with development. An ordinary fine rose-tap may be used, but far finer results are obtainable by means of an ordinary fine spray diffuser, as it is more under control, and one can vary its force more by altering the distance between the same and the paper. Whichever be used, great care must be taken, as development proceeds, to watch the print carefully, as too much may be easily washed off.

If a stream of water is used it is advisable to use a jug or can—drawn from a tap is, as a rule, far too strong. It is difficult to obtain regular action with this method, however. If a stronger one is required, about five to ten parts of finely sifted sawdust should be added to 1,000 parts of water, and this allowed to fall on the print held at angle from a greater or lesser height, according to the action desired.

If a brush or cotton-wool swab be used, then the print should be left for about half an hour in cold water, then taken out, laid face up on a sheet of glass, and there used.

With all mechanical modes of development there is a shorter scale of gradation, and the grain of the surface of the paper is more apparent.

### Gradation Variations by Sensitising and Development.

The different methods of development, combined with varying proportions of the ingredients of the sensitiser, enable one to obtain very different scales of gradation.

If a piece of gum-bichromate paper is exposed under a Vogel actinometer, the blackness of the print is measured in the usual way, and the points joined up, there will be obtained a curve, as shown in the following figures. Fig. 1 shows a characteristic curve

of a gum print, the curves *a*, *b*, *c* being those obtained on Schöller-Hammer paper—*b* with normal quantity of gum, *a* with less gum, and *c* with more gum, all with normal development.

It will be seen from these curves that *a* gives no pure whites, but a relatively long gradation; *b* shows flatness in the high-lights, from 20.14, with strong contrasts in the half-tones. If this paper

Fig. 1.

is printed under a negative so that the high-lights are comprised between 20 and 14, they will be very flat and so faint that they can hardly be seen. If they fall between 14 and 9 they will be full of contrast, and there will be a faint colour fog. Curve *c* gives a hard, clean image, and *d* shows the sensitive mixture coated on Zander's paper more highly sized. Thus it will be seen that the greater the sizing the stronger the contrasts and the shorter the scale of gradations.

Fig. 2.

Fig. 2 shows the curve of a mixture of Berlin blue and burnt sienna, with normal gum on Schöller-Hammer paper; *a* shows the gradation with normal development, and *b* the gradation with the same time of exposure, only with mechanical brush development after half an hour's soaking in water.

The curves *a*, *b*, *c* of Fig. 1 and *a*, *b* of Fig. 2 are typical of papers with weak sizing. The typical curve on more strongly-sized paper is shown in Fig. 3—*a* for normal and *b* for greater quantity of gum.

Fig. 3.

### The Effect of Sizing.

The influence of the sizing of the paper in conjunction with the gum and colour is plainly seen from these curves. A thinly-sized paper, as well as a thicker-sized one, gives with a greater proportion of colour than normal, and normal development a tint in the lights. With normal composition of the film pure whites are obtained with well-sized paper. With weaker sizing there is a peculiar flatness of the lights, which, if insolation is pushed so as to obtain contrast, becomes a uniform tint. With lessened colour this flat part of the curve disappears, the lights are clean, and the scale shortened. With mechanical development with thin-

sized papers the scale of tones is lengthened and more even; on well-sized paper it becomes shorter.

It is very instructive to expose strips of the paper under a graded photometer and then develop normally and mechanically, and note the result. The photometer or actinometer used by Dr. Köster is Vogel's, in which each succeeding step transmits four-fifths of the light of the preceding one.

In the ordinary way, on gum paper, only five to seven, or at the most ten, will be printed out under this actinometer, whilst with albumenised or P.O.P. 12-18deg. will be obtained, so that such negatives cannot be printed out on gum paper to give a correct reproduction; either the high lights will be printed out and the

Fig. 4.

half-tones and shadows be indistinguishable masses, or the shadows will be distinct and the half-tones and lights wanting.

To remedy this state of things two or three printings must be resorted to in order to render the complete scale of gradations in the negative. Thus, supposing that a negative is to be printed from which corresponds to 15deg. Vogel, and the single printing gives 5deg., then three such printings will give 15deg.

#### Multiple Printing.

The three separate sensitising can be done without any intermediate treatment of the prints, as when the print is once dry neither hot nor cold water, nor brush nor spray will touch it.

In order to explain the action of successive printings, recourse must again be had to our actinometer. Supposing that a strip of gum paper be exposed so that the gradations from 11deg. to 17deg. are represented, then 1deg. to 11deg. will be all of the same depth, 11deg. to 17deg. varying in gradation, and 17deg. to 25deg. white. If after development this be again coated with a similar sensitive mixture and in similar thickness, and printed under the actinometer 5deg. to 6deg. shorter, 5deg. to 11deg. will be gradated, so that now, by the addition of the second to the first printing, we shall have twelve gradations in all—namely, from 5deg. to 17deg. By proceeding on

these lines and using very thin coatings, it will be possible to obtain the complete scale from 1deg. to 25deg., which is not possible with any other printing process. Care must be taken, however, that, no matter how the many printings are used, the deepest tone obtainable thereby is that which the deepest shadow should have.

In Fig. 4 AB represents the degrees of Vogel's photometer and the logarithms of the incident light. The first printing will be represented by the curve AMN; HJ represents the blackness of the print. A second coating, printed 5deg. shorter, would, were the papers white, be represented by the dotted curve; but as the first impression is already there, the blackness of the second printing must be superimposed on the first. The upright CD must then

Fig. 5.

fore be reckoned from  $C_1$ , as  $C_1$ ,  $D_1$ , and so on. If, now, the points  $E_1$ ,  $D_1$ ,  $G_1$ , are joined up, we shall obtain a new curve which represents the final gradation of the print.

It has already been pointed out that the number of gradations remains approximately the same, whether the sensitive film be thick or thin, and that with thick films the gradations are inclined to sink. If, thus, in Fig. 5, AMN represents the gradation curve with a medium thickness film, that of a thinner film, printed for a shorter time, will be shown by the dotted curve. If this is now superimposed on the former, we obtain the curve AMG of the final print.

The curve which is thus given by double printing is no longer straight, but so bent that it gives soft shadows.

It is thus possible to first obtain a soft print, then a hard one and then for the third use a soft curve, so that it is obvious that one may obtain any curve that is desired, or, in other words, any desired effect, if only it is borne in mind that the length of the gradations of each individual printing can be shortened by increase of the amount of gum or the size. The curve AMG of Fig. 5 shows the superposition of a long, soft scale of tones on a short, hard scale.

## COLOUR PHOTOGRAPHY.

### A MODIFIED PINATYPE METHOD.\*

JUDGING from what has already been written concerning the process of pinatype, there seems yet somewhat more to be said with regard to this process of polychromy, which is really extremely interesting and capable of giving very satisfactory results.

Without trenching upon anything that has already been published with regard to this process, it is possible to suggest a method of utilising it, which is fairly easy; and for making prints on paper, not by successive imbibition, but simply by transfer from the glass on to the paper of a composite image, printed in the necessary successive operations on one piece of glass, which acts as the temporary support.

Obviously, when utilising the colour saturated print-plates for printing on to paper, it is only possible to attain, without ulterior aid, to a certain luminosity, which is extremely interesting and which may be applied artistically; but it is not possible to obtain prints at

all comparable, either in brilliancy or depth, to those developed on glass.

The following is the method I suggest: A sheet of glass, somewhat longer than that required for the actual print, should be thoroughly cleaned, then polished with talc, and finally coated with a 2 per cent. collodion, and on this collodion, which must be provided with a safe edge, must be coated a film of bichromated gelatine of the following formula:—

Gelatine, good hard .....	5 parts.
Ammonium bichromate .....	2 parts.
Water .....	100 parts.

The gelatine should be first soaked in the water, then melted by the aid of heat, and the bichromate added and the mixture filtered.

The collodionised glass should be placed on a carefully levelled support, and 100 minims of the above bichromated gelatine coated on every 16 square inches of surface. When the gelatine has set

\* M. Vidal's article was written before the appearance of the process advised for preparing pinatype transparencies.—Eds. B.J.P.

the plate should be reared up to dry in a dark and fairly warm place.

The first print should be either the red or blue, and after the plate has been exposed, by the aid of an actinometer, it should be washed with acid sulphate of soda to decolorise those parts of the image which were affected by light, and it should then be stained in the pinatype red.

It is advisable to rinse the plate from time to time and place it in a dish of clean water, film down, on a sheet of white paper, so to judge of the intensity, as this is better than looking through. When the desired intensity is obtained, the plate should be washed and allowed to dry, and then immersed for five minutes in a pinatype fixative, again washed and dried.

The plate again levelled should be again coated with the bichromated gelatine, and allowed to dry and then exposed under the second, the blue, transparency. It is advisable to use a magnifying glass to ensure absolute registration of the images. The red plate should be supported between two plate boxes, for instance, over a sheet of white paper, and after approximate coincidence has been obtained, the final adjustments should be made with the eye-piece, and the glasses or one edge fastened together with a lantern slide binder, or a variety, after which it should be again examined with the eye-piece, to make sure that there is no shift, and then it should be exposed with or without a printing frame.

After exposure, the procedure is precisely the same as indicated above for the red image. The blue image appearing in contact with

the red it is easy to judge of its intensity, and the plate should be well washed and then laid face down on white paper, otherwise it is easy to spoil the print.

After development the fixative should be used, and the third film of bichromated gelatine should be coated on the top of the two images and dried and exposed under the yellow transparency, and stained and treated as the others. It is extremely easy to judge of the intensity of the staining by placing the plate, film down, on paper. The plate must be again washed and treated with fixative, and then coated with a plain 3 per cent. solution of gelatine. This film acts as an adhesive medium for the final print. Any gelatinised paper or the pinatype papers are excellent as the final support. It is only necessary to soak the papers in water, and the composite image, and bring the two into contact and then squeegee well, so as to obviate air bells, and then dry between blotting paper. When absolutely dry, the margins should be cut right through with a sharp knife, and the print stripped.

In order to avoid accidents it is advisable to use a cutting glass of the exact size of the print required, and by this means one avoids the possible mischance of one side lifting before all four are cut through. If plate glass be used the surface is very brilliant, possibly too much so, but it is extremely easy to reduce this effect by using ground glass for the primary support.

It is hardly necessary to apologise for the exact and minute directions given above, for I know from experience that beginners are very easily discouraged by failures due to insufficiently precise instructions.

LEON VIDAL.

## PROFESSIONAL COLOUR PHOTOGRAPHY.

On the opening of the St. James's Studio of the Rotary Photographic Company took place on Friday last, May 11, when a company of artists, photographers, and others interested in the enterprise assembled at 45, Old Bond Street to inspect the handsome suites of rooms and witness a demonstration of the process so far as concerned the assemblage of the three monochrome prints. To the effect which appeared in our last issue it only remains to add some particulars of the premises and of the appeal which the company make to the public. No expense has been spared to provide a luxurious background for the business which it is proposed to conduct in the establishment. The decorations of the reception rooms, studio, and dressing rooms are done throughout by Waring, and are in a good taste which one expects of this experienced firm.

Of the specimens which are displayed in the large reception salon, we are portrait studies from life, and partially represent the result of the short private practice which has been possible to the company before the opening of the studio. Judgment of colour values and of truth to colour impression being superlatively personal, it is difficult to criticise or appreciate these results. We believe that as far as an appreciation as any which can be expressed is to say that the effect they produce is unlike anything with which we are familiar in photography. They are distinct in their appearance from coloured photographs. They may not be considered perfect reproductions of colour of the sitters. Probably their makers will readily admit that to be the case and equally maintain that while feminine weaknesses possess their present very positive character, any firm which seeks to enter the field of colour portraiture unprepared to temper justice with mercy might about as well go out of business. It is conceivable that the concessions which are made to personal vanity in ordinary monochrome photography can be swept away all at once when the production involves colour rendering. Assuming the portraits displayed on the walls to be honest attempts at facsimile portraiture, we think they must be very good indeed, probably a good deal better in this respect than they need be for commercial purposes. It is not likely that in colour portraiture the duties of the retoucher will be dispensed with, any more than in photography now generally practised. Perhaps the particular needs and

methods of retouching three-colour negatives will call into existence a new class of worker, whose labours, we hope, will meet with a fitting monetary reward.

In the reproductions of paintings the colour process of the Rotary Company is seen at its best, we think, a fact which points to the justness of our conclusions that in facsimile work the process in capable hands is good enough. The least satisfactory examples shown in Old Bond Street are the landscapes and other outdoor subjects, a field in which, so we should surmise, the staff of the studio has had the least practice.

It may interest the profession if we quote the prices which it is proposed to make for portraits in colours in the new studio:—

One cabinet portrait, two guineas; further copies, one guinea.

One boudoir portrait, six guineas; further copies, two guineas.

As we mentioned last week, however, portraiture is not the only card which is to be played in the new enterprise. The reproduction of objects of vertu, curios, paintings, and the hundred and one strange and rare things which wealthy man collects and desires preserved is one of the immediate tasks to which the staff are applying themselves. We hear other photographers in the provinces are equipping themselves for the practice of three-colour work with a view to introducing it into their business, among whom the firm of Heath and Stoneman, of Plymouth, to whose work we referred last week. We have since received from them several specimens of colour portraiture, which we have examined with a good deal of interest.

We would also refer to a letter received as we go to press from Mr. Otto Pfenninger (Lombardi's Studio, Brighton), in which he points out that this studio was opened for portrait colour photography in July, 1903. The exposures were made in a quarter-plate one exposure camera of home construction, and the negatives were printed from by the processes of Dr. Jumeaux and of Lumière. Four colour portraits were shown at the annual exhibition of the Hove Camera Club in 1903. Mr. Pfenninger sends us a specimen of his work done about this time, which, while somewhat predominantly red, is interesting as verifying his claims to have been early in the field with three-colour applied to commercial portraiture.

THEIR Royal Highnesses the Prince and Princess of Wales have graciously accepted two of the photographs taken by Mr. G. H. Sanford, Boscombe, at Portsmouth on their return from India.

A PECKHAM photographer named Tomlinson committed suicide last week by taking cyanide of potassium. The deceased had been in a despondent state for some time.

## FOREIGN NOTES AND NEWS.

### Local Reduction.

Wurtz recommends in "La Photographie" the use of a pad of absorbent cotton wool, saturated with absolute alcohol, and he lays great stress on the importance of this and tripoli powder. With this, halation or local dense places can be reduced without showing any scratches or other marks, as the tripoli is so fine. Failing tripoli, he suggests the use of a tooth powder. It is as well also to cut three scrapers out of hard wood, as shown in the accom-

panying figure half their natural size. Round these should be wound the cotton wool, which is then dipped into the alcohol and tripoli. It is possible to scrape down quite fine spots and places with one of these, which are shaped like a pencil, a stump, and the left-hand one shaved off to a wedge shape. This "white retouching," as the author calls it, should be performed before the ordinary retouching with pencil.

### Gürtner's Two-colour Process.

A German patent has been granted to the Chemische Aktien vorm. Schering for a method of making the necessary printing materials for Gürtner's two-colour process, on transparent supports, such as celluloid, mica, etc. Two monochrome negatives are made in the usual way through violet and red filters. From the yellow negative a print is made on ordinary P.O.P. This is fixed with ammonia, which gives the yellow monochrome picture. A celluloid film, coated

with a stripping gaslight emulsion, is exposed in contact with the blue negative, developed and fixed. The image is then converted into the well-known blue by means of ammonio-citrate of iron and potassium ferricyanide, laid film down on the yellow print, squeezed and allowed to dry. The celluloid is then stripped off.

### A New Non-stripping Carbon Tissue.

Bühler, of Schriesheim, has introduced a new non-stripping carbon tissue, which allows the image to be seen during printing, thus doing away with the necessity for an actinometer. The paper is first immersed in methylated spirit for a minute, then sensitised in a 2 per cent. solution of potassium bichromate and dried. The paper must be exposed till the details are distinctly seen of a brown colour in the high lights when examined by transmitted light, practically one must print about twice as long as with P.O.P. After printing, the tissue should be immersed in cold water for a minute or two, and then in water at about 100 deg. Fahr., in which the print will develop slightly, and must then be sprayed with a fairly strong, but fine, stream of cold water. It is stated by Professor Schmidt, of Karlsruhe, that there is much greater transparency in the shadows than usual, and that the paper will give two grains—one coarse for large work, and the other fine for small.

### The Spectra of Luminous Bacteria.

Molisch, of Vienna, has been examining the light emitted by the luminous bacteria of decaying flesh, fish, and wood, and finds that practically it is confined to the yellow, yellow-green, and green parts of the spectrum; there is no red and no violet to be seen. It is, of course, extremely difficult to accurately determine the limits, because the light is so weak, being about 0.000785 Hefner candles per square millimetre. It was found possible to obtain a very good photograph of a thermometer with the light emitted by the bacterium phosphoreum with a rapid plate and a lens working at  $f/5$  with fourteen hours' exposure.

## New Books.

"The Photographic Picture Postcard." By E. J. Wall and H. Snowden Ward. London: Dawbarn and Ward, Ltd., 1s.

This handbook of the omnipotent picture-postcard is divided into two distinct portions. First, the technical, which deals with the production of picture cards by the usual, and by some unusual, photographic printing processes. The second part concerns the business of picture postcard manufacture and sale and the sale of reproduction rights in photographs to postcard publishers. Of the technical section, the most valuable chapter we find to be that describing methods of colouring postcards. We confess to feeling a little dissatisfied with the others, which amount to nothing more than a series of brief notes on the various printing processes. We should have wished to have seen some hints on the special difficulties of the postcard printer, such as the marking and discolorations on the plain side of the card and trouble in getting the cards to dry flat. But we cannot find them. We would recommend the inclusion of such matter in place of notes on "Woithly" and other "types," which we conceive to be processes of little value to the postcard maker. The latter part of the volume, dealing with the business in postcards, however, contains a number of suggestions and items of information which cannot fail to be read with profit by those who are about to embark, or who have embarked, in this branch of "photography for profit." For example, we can commend the hints on the choice of a photo-mechanical process for postcard production as eminently sound advice on important matters in regard to which our advice is not infrequently sought. For the guidance which it gives in this direction only the book should be worth a good deal more than the price charged for it to anyone who is connected with the commercial production of postcards.

"Bombay Ducks, or Birds and Beasts found in a Naturalist's El Dorado." By Douglas Dewer. London: John Lane. 16s.

Mr. Dewer's book deals with the manners and customs of "Bombay Ducks," which expression, it must be explained, is not used in its former Anglo-Indian sense of inhabitants of Bombay, nor in its present-day meaning of certain brittle pieces of sundried fish largely eaten with curry in South India. The "Bombay Ducks" of the book are the birds of the "Bombay side," the author essays having appeared first in various Indian newspapers. Probably our readers will be interested as much by the photographic illustration of Colonel R. S. F. Fayer as by the narration, in entertaining fashion, of the author as to his many bird friends. The volume gains immensely in interest by the inclusion of the plate-illustrations from Colonel Fayer's photographs, for one obtains a lifelike impression—of the hoopoe, for example—which pages of literary description could hardly replace, though they admirably supplement it. "Bombay Ducks" is quite a readable book of bird life.

"Photochemie." By Dr. J. M. Eder. Halle: Wilhelm Knapp, 15s.

This is the third edition of the second part of Dr. Eder's famous handbook, and was previously issued as "Die Chemischen Wirkungen des Lichtes." The second edition, which was published in 1891, was only about 300 pages, but so much has the literature on this subject grown that now we have a volume of close on 600 pages. The very latest papers are noted, including all those upon the many radiations, which act upon the plate, but which may still be questioned as to whether they are light; ions, electrons, and gaseous ions are also treated of. There are, of course, many facts recorded which have but little connection at present with practical photography, but to the earnest student this volume will, like all the others of this work, prove an indispensable reference work of great value, to enable him to learn what has already been done by others.

## Exhibitions.

### THE MUNICH FINE ART EXHIBITION.

We are pleased to welcome the examples of German art now on in the Grafton Galleries. Whilst widening our purview, such national displays tend to break down prejudice, and carry the realising advantage of catholicity of taste and of new points of view. German art has always excelled in three things: in romantic imagination, in decorativeness, and in realistic presentment. In that thing and logical imagination which can take a myth of antiquity fashion it in paint so that it speaks convincingly to minds of aerial and unpoetic mould, the re-creations of men like Boecklin, Schik, and Hoffman von Vestenhof, are pre-eminently rich. The "Minotaur," by the last-named, is shown in an arena, his man's head lashed out horizontally to oppose the onslaught of his adversary. The crushing weight of his great bull-body is made appallingly lent. Similar truth exists in Franz von Stuck's "Fight for the man." We feel no doubt that primitive man was just this sort of hairy brute, and that this woman, though fair of skin, might look at a contest for her possession with just such a brutally beautiful expression, but mild indifference and placid interest in its result. The realism of more ordinary things also is here abundant, in manner and new. Still life by Grützner (of Falstaff fame), beyond which it is impossible to believe that painting can go, and beside which photography, in actual realisation, limps and falls short. Of more modern aspect we may point to the "Swans" of Rudolf Schramm, life size marvels of colour, tone, movement, and general truth of effect. There are some great achievements in landscape, embodying the romantic idea, as in Uhl's "Peaceful Evening," where a shepherdess reposes upon a hill top in a twilight rendered with astounding truth of feeling. Before the "Mid-day Hour" one is reminded of the subjects chosen sometimes by Demachy and by J. M. W. Turner. Here a nude girl sits upon the marble edge of a fountain, her feet in the water, and herself almost hidden in the shade of pink chestnuts in bloom, whose branches hang over the water. The stillness is suggested unmistakably. Fritz von Kaulbach is well represented, as also is Franz von Lenbach, the finest of whose portraits is, to our minds, undoubtedly the "Bismarck." The exhibition is most interesting, however, in regard to its landscape work, which has a loftiness of intention peculiarly its own.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes.*

The following applications for patents were made between April and May 5:—

**PHOTOGRAPHY.**—No. 10,030. Improvements in photography. William Theophilus Ord, Greenstead, Madeira Road, Bournemouth.

**SELF-TONING PAPERS.**—No. 10,051. Improvements in self-toning silver chloride printing papers. Oskar Hermann Steudel, 13, Featherstone Buildings, High Holborn, London.

**TYPE PRINTING.**—No. 10,078. Improvements relating to the reproduction of pictures by the aid of catalytic action. A. G. Bloxam, for the Neue Photographische Gesellschaft, Berlin.

**DEVELOPING TANKS.**—No. 10,123. Improvements in photographic developing tanks. Thomas Jackson and Robert Ley Wood, Lloyds Bank Chambers, Cheltenham.

**FIXING PLATES.**—No. 10,153. Apparatus for washing or fixing photographic plates. H. C. Heide, 1, Broad Street Buildings, London, for Martin R. Jacobus, United States.

**DEVELOPER.**—No. 10,234. Photographic developer. Karl Busson, 216, Friedrich Strasse, Berlin.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**ONE-TABLET DEVELOPERS.**—No. 3,164, 1905. The claim is for a solid compacted developing composition in dry or tablet form containing borax as a preservative alkali or accelerator, and only requiring the addition of water. The invention may be carried out by the preparation of tablets containing (in each of the size for 4-plate) metol, 2 grains; hydroquinone, 4 grains; potassium metabisulphite (powdered),  $\frac{1}{2}$  to 1 grain; borax, 10 to 20 grains; colloid, such as gum, tragacanth, or like adhesive, q.s.; glycerine, or other hygroscopic medium, e.g., glucose syrup, q.s. (optional for assisting solubilities). Mix the dry ingredients, add the colloid and glycerine (about two drops of a saturated solution of gum arabic, and one drop of glycerine suffice), then add alcohol continuously, and stir to avoid precipitating the colloid, in sufficient quantity to make the mixture into a paste. Then press the mixture into contact with glass or other moulding surface for shaping the paste into tablets if desired, said mixture being allowed to dry therein, and when dry, ready for use. William Fraser Cloughton Kelly, 22, Winchenden Road, Fulham, S.W.

**ROLLER SLIDES.**—No. 3,165, 1905. The chief claim is for a hollow or tubular bobbin furnished with a "roll film," and containing the necessary chemicals for development. According to the invention the central portion of the bobbin is constructed of hollow section, and serves as a receptacle for a sufficient quantity of developing chemicals to bring out the latent images on the whole length or roll of film; the hollow central portion or receptacle being closed at the extremities by the end flanges pertaining to the bobbin. One mode of constructing a bobbin consists in forming the core, or hollow, or tubular portion of perforated material—ordinary perforated zinc—covered with paper or the like so as to retain the chemicals; a projecting thread serving as a convenient means of rapidly tearing or removing the paper covering. When it is desired to develop the roll of film, the core or central portion of the bobbin may be divided or the ends removed; the opening of the bobbin rendering the developing chemicals available for use. The latter are then immersed in water contained in a suitable vessel, and so form the developer. William Fraser Cloughton Kelly, 22, Winchenden Road, Fulham, S.W.

**EMULSION PAPERS.**—No. 7,693, 1905. The claim is for a "process for the manufacture of sensitive gelatine emulsion papers, which shall be capable of readily taking water-colours, characterised by the fact that, omitting any baryta layer, unsized paper is coated with gelatine emulsion, thereby obtaining simultaneously a single sizing of the paper and a penetration of the entire thickness of the paper with gelatine and salts sensitive to light, whereby the colours are able to penetrate the fibres of the paper to a greater depth." In applying the gelatine emulsion to unsized paper (which, owing to the decreased strength of such papers, is done with the assistance of a support) not only does the gelatine penetrate deeper into the paper, but, what is exceedingly important, the sensitising medium also, than is the case with sized paper, which always comprises a baryta layer in addition. This latter is quite absent in the present case. Both the gelatine and the salts sensitive to light become uniformly distributed throughout the entire thickness of the paper web, solidify the fibres and render the manufacture much more economical, make colouring easier and more pleasant, and finally result in much thicker coats of colours which will not fade so readily. Quite apart from the question of colouring, however, copies or reproductions made upon such paper may also be retouched with water-colours very readily. Ludwig Robicek, 7, Kirchengasse, Vienna.

**CAMERAS.**—No. 405, 1906. This invention relates more particularly to that type of auxiliary flap or shutter which is permanently and in normal position across, or covering, the lens aperture when the camera is not in use, and is only removed simultaneously with the operation of the blind shutter to give an exposure, and

is immediately returned when the exposure is complete. It consists essentially in applying an extension to the lever or mechanism of the blind shutter to engage direct with the auxiliary shutter and move it from the lens aperture slightly in advance of the release of the blind for an instantaneous exposure, and return it again as soon as the blind has completed its travel and the releasing lever returns to normal position. The Thornton-Pickard Manufacturing Co., Ltd., Altrincham, George Arthur Pickard, and Frank Slinger.

#### CATALOGUES AND TRADE NOTICES.

The receipt of the new issue of the photographic catalogue of Messrs. W. Watson and Sons, 313, High Holborn, London, W.C., is a reminder of recent progress made by this old-established firm in apparatus for professional and amateur photography. Of certain of these—the "Actinolux" lens and the hand-camera "Antinous" release—we have already spoken in these columns or in the "Almanac." Of others we shall have to report upon before long, but meanwhile we may advise application to Messrs. Watson for this twenty-sixth edition of their price list, notably for particulars of a new series of the "Holostigmat" lens, embodying large aperture and convertibility, the separate components being available at their full aperture on the same size of plate as the doublet of which they form part. Another new lens in the list is the "Holos" Convertible wide angle, examples of work done with which in the combined and separate forms are given. The "Empire" hand camera, specially designed for the tropics, is also fully specified in the list.

The makers of the Page-Croft pigment paper are making a special offer of six assorted half-plate pieces of paper for 6d. The packet can be had from dealers or from the factory, 394, Cooksey Road, Birmingham.

From the firm of Billcliff, Richmond Street, Boundary Lane, Manchester, we have received a new catalogue of apparatus for midget, stamp, and postcard photography. The firm has a special and varied series of repeating backs suitable for all classes of cameras, and supplies also printing frames for use with those pieces of exposure apparatus. Enlargers, adapted to work from midget negatives, and bromide printing machines are also specialties of the firm which are listed in the catalogue.

**FIRE at Gloucester.**—A fire which might have resulted in serious consequences broke out at Messrs. F. W. and S. Longman's photographic studio in Clarence Street, Gloucester, one evening last week. It appears that Mr. Longman had lit a stove, which had been in constant use, in preparation for a chess club meeting which was to have been held there in the evening, and, returning to the studio after being away for a few minutes, found the wall of the studio in flames. Both fire brigades were quickly summoned, and with their help the fire was soon extinguished. The principal damage was to the glass roof. Some furniture was injured, but none of the photographic plates and apparatus were near the fire.

**THE Autumn Exhibitions.**—We have a few copies of the entry forms and prospectuses of the R.P.S. Exhibition and The Photographic Salon, a copy of each of which we shall be glad to send to any one on application.

**MR. H. O. KLEIN**, the well-known collodion emulsion expert, sailed for New York on May 8, having been sent out by Messrs. A. W. Penrose and Co., Limited, to assist their agents in introducing collodion emulsion and other Penrose specialties in the United States. He will probably remain about three months in the States, and will visit the most important centres of photo-engraving. He will make his headquarters with the United Printing Machinery Company, 12, Spruce Street, New York, the sole agents in America for the Penrose goods.

At the monthly meeting of the Printers' Managers' and Overseers' Association, held on May 1, a lecture was delivered on "Celestial Photography" by Mr. Percy Morris, F.R.A.S., a director of the firm of Messrs. Whitehead, Morris and Co., Tower Hill, London.

## New Apparatus, &c.

The "Premoette." Sold by Kodak, Limited, Clerkenwell Road, London, E.C.

Under this name, Messrs. Kodak, Limited, have brought out an addition to the series of well-known Premo cameras the notable feature of which is its small proportions and simple construction. The "Premoette" takes negatives 3½ in. by 2½ in. and is made to take the "Premo" film pack of this size, the whole apparatus, with the pack in position, being then self-contained and

equal to producing a dozen exposures. Thus the camera is in line with other Kodak instruments in being daylight-loading and extremely portable. The new camera is fitted with a single lens shutter, with everset instantaneous, time, and bulb movements, and a series of four stops. It has finder for horizontal and vertical pictures and a focussing scale which is sufficiently marked for the intensity of the lens. The "Premoette," which sells at a guinea, should be popular as gift for those making a first acquaintance with photography.

THE new-style series of developing tanks, which was introduced by the Kodak Company last year, has been added to by the introduction of a larger size capable of taking spools up to 7 in. Hitherto spools over 5 in. have had to be machine-developed in the well-known Model H apparatus, but the new tank now renders the latter system as applicable to all the commercial sizes of spools as it

predecessor. The new tank, it may be added, is an improvement on the earlier smaller sizes in that it is necessary only to invert two or three times during the twenty minutes' development, not to remove the film and the enclosing apron from it. This is done by the aid of the watertight lid shown in the figure. The price of the new tank outfit is 32s. 6d.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

Name of Society.	Subject.
Aberdeen Photo Art Club .....	"Gum Bichromate." Mr. J. Dalgity.
North Middlesex Photo. Soc. ...	Outing to Mill Hill.
South London Photo. Society ...	Outing to Leigh-on-Sea.
Chelsea and District Photo. Soc.	Outing to Brentford—River and Canal.
Birmingham Photo. Society. ...	Half-day Excursion to Offchurch.
Redhill and District Cam. Club	Outing to Friday Street.
Bristol Photographic Club .....	Outing to Providence Hill.
Manchester Amat. Photo. Soc.	"Portraiture." Mr. T. Lee Syms.
Southampton Camera Club .....	"Exhibitions and Exhibition Pictures." Mr. F. G. Ryder.
	1. "The Theory of Fixation; Combined Development and Fixation." Mr. S. E. Sheppard, B.Sc., and G. E. K. Mees, B.Sc.
Royal Photographic Soc. ....	2. "Sizing in Relation to Print Out Papers." Mr. P. L. Thornton.
Hackney Photo. Society .....	"Side Lights on Sepia Toning." Mr. H. W. Lane. R.P.S. Competition Lantern Slides due.
Acton Photographic Society ...	"First Aid in Photographic Accidents." Practically Demonstrated. Mr. W. Polty.
Leeds Camera Club.....	"Isochromatic Photography." Mr. W. K. Skipwith.
North Middlesex Photo. Soc. ...	"Photographic Lens Making." Messrs. Taylor, Taylor & Hobson.
Cricklewood Photo. Society.....	Lantern Lecture, "North Devon."

## PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

### DEPUTATION FROM THE ACTORS' ASSOCIATION.

Friday, the 11th inst., the committee of the Association received a deputation from the Actors' Association, at the Royal Photographic Institution, 66, Russell Square, W.C. The following members of the committee were present:—Messrs. F. A. Bridge, T. Birtles (Warren), E. C. Elliott, Alfred Ellis, Martin Jacquette, P. Lankester (Bridge Wells), A. Mackie, H. S. Mendelsohn, D. Prodder, J. Camell, Lang Sims, and R. Fellows Willson; Mr. Martin Jacquette, president, in the chair. Messrs. C. Blakiston, Hayden Coffin, A. Holmes Gore represented the Actors' Association.

Mr. Holmes Gore, in introducing himself and fellow delegates, said the Actors' Association consisted of some 1,600 members of the profession, and was governed by a council comprising a president (Mr. Bancroft), 12 vice-presidents, and 42 ordinary members, many of whom were many London managers. The association had existed for many years, being incorporated as a company in 1891. It had been a constant source of complaint in the profession that the regulations governing the relations between photographers and actors bore very harshly upon the latter, and it was with a view to meeting that many of the difficulties at present existing might be removed, that a sub-committee was appointed by the Actors' Association to draw up some suggestions, whereby an agreement might be reached to avoid the causes of friction and leave them very much satisfied and safer in the future.

Mr. Gore then read the suggestions for dealing with the relations between the photographic profession with actors. Continuing, Mr. Gore said there was another point which had arisen, and which they would like to lay before the P.P.A. It was that in the agreements with managers of companies for the photographs of companies in groups for the purpose of reproduction in magazines, etc., they desired very much to limit the sale of photographs after the price had been withdrawn, and thus confine the sale of photographs to the purposes for which they were taken—that was, for the purposes of advertising the particular piece for the benefit of the actors engaged in it, and not for the benefit of the production. They found that long after a piece had been withdrawn the photographs were being used (by some reproduction firm possibly) for commercial purposes and not for the required purpose for which the photographs were taken. Their sitting was for the benefit of the piece, and the photographs of plays were sent round the country, with the exception of the London actors omitted. For instance, if he (Mr. Gore) were taking one of Mr. Alexander's parts in a play on tour, Mr. Alexander's portrait would be shown instead of his own in the program character he was playing. There were five questions

which they would leave to the committee, and would be glad if they would consider them and let them have replies.

Mr. Jacquette said they were very pleased to see the members of the deputation, but he ought to state that photographers were very much governed by the state of the copyright laws, as they were framed at present. He could assure them that the questions placed before them would receive sympathetic consideration. It seemed to him, however, that some of the matters were rather questions for consideration between the Actors' Association and the theatrical managers.

Mr. Hayden Coffin spoke with regard to picture postcards. They had just seen from particulars of the latest Budget that the Government increase was greatly benefited by the sale of picture postcards, and they desired to protect themselves, as well as the Association. The managers, most of them, think they cannot get the co-operation of the artists, and the artists suffer very severely. There were many actors walking about only anxious to jump into other's shoes, and if those in engagements showed a disposition to stand on their rights they soon received notice to quit, so that the actor was very awkwardly placed with regard to such matters. They would like the P.P.A. to make a very strong case with the managers for the sake of both sides. The ladies would be only too pleased to make better terms. The system upon which some of the play pictorials were produced was very harmful. After a play had finished its run certain pictures remained very popular. The sale of these pictures ought to benefit the photographer and actor, especially when the manager had no further need of them. He thought a mutual understanding would avoid much litigation and unpleasantness.

In conclusion, Mr. Gore said that in laying these suggestions before the P.P.A. he wished to lay stress upon the fact that it was in the friendliest spirit they approached the representatives of the photographic profession and in the hope that the Association might help them. The deputation then withdrew.

The usual monthly meeting of the committee of the P.P.A. was then held, at which the same members were present.

The President said his first duty was the painful one of referring to the severe loss the association had sustained by the death of their hon. secretary and treasurer, Mr. Wm. Grove. As their colleague in the work of carrying on the business of the association, Mr. Grove's assistance had been of inestimable value. The interest he had felt in the progress of the movement had been testified by the work he had performed for them in carrying out the duties of the various offices to which they had appointed him. But beyond their esteem for him in his official capacity every member of the committee would feel that a personal friend had passed away. His high character and amiable disposition had endeared him to all. A wreath had been sent in the name of the Association, and he (the president) would now move that a letter be written to Mrs. Grove, expressing their deep sympathy in her bereavement. The resolution was carried in silence.

With regard to filling the vacant offices of hon. secretary and treasurer, the president moved that Mr. Lang Sims be elected as hon. treasurer, and Mr. Alex. Mackie hon. secretary. These gentlemen, having signified their willingness to serve, these appointments were agreed to. Certain changes rendered necessary by the new arrangements and other domestic matters were then discussed, and a sub-committee was appointed to consider the proposals of the Actors' Association and report.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, May 15, the President, Major-General Waterhouse, in the chair. A lecture illustrated with lantern slides was given by Mr. F. Dunsterville on "By Paths in India."

THE HOVE CAMERA CLUB has held a prosperous year, as is shown by the report and balance-sheet just published. The club is unfortunate in losing the services of Alderman Colman, J.P., who has happily filled the position of president for five years. His place has been taken by Mr. A. R. Sarjeant, who resigned his post of hon. secretary, through pressure of business, and to whose energy the club owes much. Mr. R. C. Foskett, who has held the post of assistant hon. secretary and treasurer, also retires, but his services are retained on the committee. The post of hon. secretary has been

taken by Mr. W. H. Bone, of 32, Sackville Road, Hove, with Mr. G. W. King as assistant hon. secretary, while Mr. F. L. Jermyn has accepted the position of hon. treasurer.

**WORTHING CAMERA CLUB.**—At the annual meeting a very satisfactory report was presented and the following officers elected:—President, Colonel Henty; vice-presidents, Sir Henry Aubrey-Fletcher, C.B., M.P., Mr. Hector Morison, J.P., Mr. H. Foreman, Alderman E. C. Patching, Councillor W. Gardiner, Councillor F. Tate, Councillor G. H. Warne, Dr. W. A. Gostling, and Mr. F. W. Patching; committee, Messrs. H. G. Loader, A. C. Osborn, H. Swain, N. L. Watts, C. Spencer, and R. Long. The honorary secretary, Mr. Edmund Crouch, was re-elected, and an expression of the club's appreciation of the successful services for the club was offered in the shape of an illuminated address.

**CROYDON CAMERA CLUB.**—"Odds and Ends," by members of the council, resolved itself, on the 9th inst., into a series of "talks" about various things, and a very pleasant and instructive evening was spent. First came Mr. J. M. Sellors, who showed a very convenient and eminently practical retouching desk, constructed out of wood and millboard. When knifing a negative—a delicate operation at the best—he lubricated the film with "Baskett's reducer," which facilitated matters considerably. Mr. F. Stokes followed with a paper on "Floral Photography," illustrated by lantern slides. Mr. R. H. Edgar next raised a point in telephotography, which, so far as recollection goes, does not appear to have been dealt with before. When using a Beck's "Multiflex" lens, he had for a long time been troubled with a considerable amount of general fog, whenever the sky was included in the field of view. This resulted in more or less flat pictures. On thinking the matter out he came to the conclusion that this was simply due to reflected light inside the lens tube, the diaphragm contained in the tube being insufficient to cut off all stray light. He accordingly constructed a supplementary tube, the same length as the lens barrel, and fitted it up in front. The improvement was most marked; indeed, he could now obtain far more contrasting pictures with the "Multiflex" so fitted than with an ordinary unshielded objective. When working close to the sun, he even went a step further, and placed a short tube of larger diameter, or a rectangular frame, in front of all. The contrivance did not cut off any part of the image. Mr. Mees stated he had met with the same trouble as Mr. Edgar had experienced, and had no doubt the explanation of the cause was correct. The point raised seemed to be of considerable importance to those who employed telephoto lenses. Mr. Edgar next drew attention to a peculiarity of light filters placed in front of the objective, oblique incident rays were necessarily compelled to pass through a greater thickness of tinted glass, or stained film, than axial rays, proportionally robbing the margins of the plate of actinic light. He had found this defect had obtruded itself in practice. In the short discussion that arose on the point, it was agreed that, whatever the position of the light filter, the same conditions would prevail to some extent. Mr. H. Allen, following, advocated Mr. Sterry's method of securing soft bromide prints from hard negatives, by means of a bichromate bath before development. A series of prints and graduated tints were passed round, showing that, although both ends of the scale were affected, the shadows were far more cut than the high-lights. The method he had adopted was as follows:—Trial exposures were made for the high-lights, disregarding the shadows entirely, which might be hopelessly buried. Taking a print showing the high-lights satisfactorily, as normal for the purpose, experience would indicate the necessary amount of over-exposure from the normal. The greater the over-exposure the longer the time the prints would have to be immersed in the bichromate bath. As an instance, using  $2\frac{1}{2}$  grains per ounce, double the exposure would require two minutes in the bath four times the exposure, four minutes' immersion, and so on. Mr. Sellors cheerfully remarked he had tried the "miserable process," the same results could be got with far greater certainty by variations of exposure and development. Mr. W. H. Rogers agreed; when dealing with extra hard negatives he over-exposed and diluted his developer. Mr. E. A. Salt said such a course might produce a "fine art" print, but rich deep blacks would be difficult to obtain, and the shadows must be blocked; the latitude of correct exposure was very small with bromide papers.

Mr. C. E. Kenneth Mees said that since Mr. Sterry's paper on the action of bichromate he had worked at the subject, and hoped to publish a paper shortly. He did not agree with many of the conclusions Mr. Sterry had drawn. The process was undoubtedly most uncertain and erratic, as it was almost impossible to standardise conditions. Results were influenced by the nature of the film, paper support, temperature, atmospheric conditions, etc. With the standard bath advocated by Mr. Allen he did not think it possible to get a ratio between exposure and time of immersion. The duration between immersion in the bichromate bath, and development, and the method of, and time occupied in washing after immersion, would give enormous differences in results. Under certain conditions was quite possible to reverse the remarkable action the oxidising salt had on the latent image. Probably the best method was to soak the print for a very short time in a standard bath, and wash the free salt out entirely before development. Mr. Allen, in reply, said so far he had experienced no failures, and the proof of the pudding was in the eating. Mr. H. P. C. Harpur brought the evening to close by showing a contrivance, consisting of several separated layers of black tulle, mounted in a short tube, and adjusted in front of a lens. The device had been very successful when enlarging, diffusion of focus was secured without loss of structure, and it had also wonderful action in softening excessive contrasts. He proposed applying the system to portraiture, and would later on communicate results.

**NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.**—Mr. J. Munro lectured last week on "Hampton Court Palace." He traced the history of the Palace, giving much valuable information, which was enhanced by the slides thrown upon the screen. Illustrations of interior and exterior architectural features were much admired, and the representations of its art treasures showed with what patience Mr. Munro had pursued the study of so interesting a subject. The lecture is one that will be appreciated by any society who can induce Mr. Munro to lecture before them.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Meeting held May 10. Mr. S. H. Fry in the chair. Mr. T. Thorne Baker read a paper upon "Spectro-photography and the making of light filters, including controlling methods by the Abney colour disc." The diffraction grating spectrum was used, with an arc or acetylene light screened so as to make it similar to sunlight. The author used a cell in front of the slit of the spectroscope, and added 0.5 per cent. solution of naphthol yellow, and 0.02 per cent. solution of mandarin orange, and exposed plates till the densities were equal to the luminosity curves. The correct result having been obtained to make a dry filter, the quantity of dye was calculated out as follows:—If of the naphthol yellow solution 0.15 ccs. were used, and 0.07 ccs. of the mandarin orange, then if S represents the superficial area of the liquid in the cell, the width being negligible, the

$$200 \times S \text{ gms. of naphthol yellow and } \frac{0.07}{500 \times S} \text{ of mandarin orange}$$
 were the amounts of dyes required to mix with gelatine or collodion applied to every square centimetre of the ideal filter. A filter was only correct for one plate, and the absorption of the filter would vary according to the colour sensitiveness of the plate. The method of control by the Abney disc was purely arbitrary, and depended on the personal element. The well-known principle of these discs was then described, and examples shown, and the results obtained by photographing the revolving disc with and without the filter described, and it was stated that the slightest variation in the colour sensitiveness in different batches would be obvious in the results obtained. Stress was laid upon the importance of giving normal or slight under exposure—not over, as reversal was fatal to the results. Mr. Fry asked in what colour regions plates were liable to vary. Mr. Baker replied, Practically only in the blue-violet, but that the latitudes of the plates was such that users would not get any variation. In answer to a question by Mr. Woodland as to whether filters adapted by acetylene were correct for daylight, the reply was in the affirmative. Mr. Human suggested that plate makers should coat their plates with a properly prepared gelatin filter, but the lecturer stated that although this was an ideal method it was not commercial. A vote of thanks was accorded on the motion of Mr. T. E. Freshwater, who referred to the visibility and invisibility of a diatom under green and yellow spectrum rays.

## Correspondence.

\* *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\* *We do not undertake responsibility for the opinions expressed by our correspondents.*

### A PHOTOGRAPHER'S LOCAL ADVERTISING.

To the Editors.

Gentlemen,—Perhaps many of your readers may be interested in the way I have found of profit to me in bringing my studio before the public in the town. Mine is not the highest class of studio, but I do a good business with the middle classes, and having derived many useful hints from those who have written to the JOURNAL, I may reciprocate to some small extent. The little dodge, if I may call it so, of which I now write consists of a postcard, which I have distributed to people waiting at the doors of the theatre. It

has taken the fancy of a good many people, so I have heard, and therefore I think it may be of service to other readers of the JOURNAL. The card is quite blank on the address side, save for the word "Postcard," so that it may be used for communications if desired. On the other side is a reproduction from a photograph, same I enclose, with the wording only:—

A. J. Smith, Photographic Studio, 6, High Street, Blanktown,  
A High-class Photograph at a Moderate Price.

I suppress my own name and address, as I cannot undertake to deal with any correspondence, but if the photograph is of any service to readers of the "B.J." I shall be glad to cede the copyright to any of them, it having served my purpose now. Perhaps you, Sirs, can do the needful in making the copyright free to any. I enclose a negative for that purpose, and remain, yours truly,

NORTH COUNTRY LAD.

We are much obliged to our grateful correspondent, to whose request we have acceded by paying to him a small sum of money for the negative without any provision as to the copyright. The negative is therefore destroyed, and any one may therefore make use of the "Early Doors" photograph without incurring any liability. The best course to render the subject available to our readers has seemed to us to place it in the hands of the photo-engravers, and we have therefore handed copies of the photograph to Messrs. Harold Wood, St. Bride's Works, Middlesborough, and to Messrs. Hamel and Co., Palmerston Street, Woodborough Road, Nottingham, either of whom will supply half-tone blocks from the photograph at their usual scale of prices.—Eds. B.J.P.]

### HERR DÜHRKOOP'S PHOTOGRAPHS.

To the Editors.

Gentlemen,—In the notes, "Photographic Portraiture" by R. Dührkoop," issued with the guide to the exhibit of this famous German artist, there is some information which is certainly misleading. It is stated that Herr Dührkoop employs a very large staff in his busy studio, and his prints are issued only in either

carbon, platinum, or gum. Now, as a matter of fact, Herr Dührkoop has been a constant user of various grades of our "matt-albumen" papers for several years. Also, after inspecting this interesting collection carefully, we are of opinion that some of the prints shown are on T. and M. matt papers. We hope you will find space to publish this correction.—Yours faithfully,

L. TRAPP AND CO.

(for Trapp and Münch).

Milton House, Chiswell Street, London, E.C.,

May 7, 1906.

[We are glad to give prominence to Messrs. Trapp's letter, which reaches us at the same time as a collection of prints on matt albumen papers from Messrs. Trapp and Münch, of Friedberg. The latter show the admirable results obtainable on the papers, and confirm us in the good opinion we expressed of them some time ago in these pages.—Eds. B.J.P.]

### A CAMERA CLUB IN THE WEST END.

To the Editors.

Gentlemen,—A determined effort is being made to resuscitate the Camera Club, and in the short time the matter has been in hand promises of support have been received from over fifty members of the old club.

We have the option, up to June 1, of suitable premises close to Charing Cross, which are now being rebuilt, and would be adapted to the needs of a camera club.

A meeting will be held under the chairmanship of Sir Richard Martin at Charing Cross Hotel on the 24th inst. at 6 p.m., at which the proposal for the re-establishment of the club will be fully discussed, and, if approved, a provisional committee appointed.

Those interested in the formation on a satisfactory basis of a purely photographic club for London, at a reasonable subscription, are requested to communicate at once with either of the undersigned, and to attend the meeting.—We are yours, etc.,

HENRY W. FAIRHOLME,

Blenheim Mansions, Queen Anne's Gate, S.W.,

A. R. F. EVERSHEED,

15, Great Winchester Street, E.C.

May 15, 1906.

### THE ZANDER FOUR-COLOUR PROCESS.

To the Editors.

Gentlemen,—With reference to the extract from the "Photographische Korrespondenz" you publish in the current number of the B.J.P., in which Dr. Eder alleges that my colour process is based on Hering's theory, and was anticipated by him in a lecture he gave before one of the scientific societies of Vienna ten years ago, permit me to state that, to express it mildly, Dr. Eder is mistaken. My colour process was arrived at by empirical methods independently of, and is not based on, Hering's theory. Those who are conversant with this theory, and take the trouble to compare it with my theory, as detailed in my patent specification (27,023, 1904) may judge for themselves. Moreover, from the printed report of the lecture in question (on "Colour Reproduction by Means of Photography") which has meanwhile been sent me, it is not only certain that Dr. Eder's and my views on colour phenomena materially differ, but in the same paragraph of eight printed lines, he expresses his uncertainty of mind whether Hering's theory carried out in practice would give satisfactory results. This is far from anticipating my process.

I have no wish to quarrel with Dr. Eder, or to pass any opinion on his allegation, but will take it in a philosophical spirit. Had my colour process not produced satisfactory results in practice, neither Dr. Eder nor anybody else would have troubled to allege that they anticipated me, and therefore I ought to consider Dr. Eder's assertion a compliment.—Yours faithfully,

C. G. ZANDER.

### ARTIFICIAL LIGHT IN COLOUR PORTRAITURE.

To the Editors.

Gentlemen,—With reference to the article on p. 366. of last week's issue, we think it may be of interest to many of your readers to

know that the "Boardman" arc lamps have been adopted by the Rotary Photographic Company for use in production of their natural colour photographic work, and it is thought that the light from these lamps, being far more constant in quality and quantity than that of the fluctuating quality and quantity of daylight that the town photographers have to contend with, that more constant and reliable work will be obtained.

The two outfits they have consist of our multi-carbon open arc type of lamp, having three pairs of carbons connected up in series, and running on a 200-volt direct current supply. They can be run at 20, 25, or 30 ampères, and each apparatus is capable of producing 8,000 candle-power.

For the production of a soft and well-lighted negative it is essential to use reflected light, therefore the whole of light produced is thrown into a parabolic-shaped reflector about 4 ft. 6 in. in diameter, so that no direct rays reach the sitter.

In fact, we might (for illustration) liken the light produced by the lamp to the sun, and the reflector to the clouds, and thus it will be seen that the reflected rays produce an artificial light, very closely approaching to a north light, and, with our apparatus, has the advantage of being used at either side or end of the studio.—Yours faithfully,

F. R. BOARDMAN.

10, Southwark Bridge Road, London, S.E.  
May 14, 1906.

#### SENSITISING CARBON TISSUE.

To the Editors.

Gentlemen,—I have read with much pleasure the articles dealing with the carbon process that have appeared in recent issues of the BRITISH JOURNAL.

It is stated in the article in the last issue that an excess of ammonia in the sensitising bath does not harm, as it flies off as the tissue dries. As a professional carbon printer I may say this has never been my experience.

I have always found that an excess of ammonia in the sensitising bath affects the tissue in two ways.

1. Slowness in printing, the tissue being less sensitive.
2. The resulting prints are inclined to be hard or lack half-tone.

Both these difficulties can be overcome by keeping the tissue some days before using.

I trust this will prove of interest to many workers.—Yours faithfully,

L. R. GOODYER.

6, Canterbury Mansions, West Hampstead, N.W.

[It is quite correct, as we said, that any excess of ammonia flies off as the tissue dries and does no harm. Most experienced carbon workers know quite well that, when the tissue is sensitised and dried under the most favourable conditions it works better, and is also more sensitive after two or three days' keeping than it does directly it is dry, as then it is apt to be in a too soluble condition, and unless great care be used in the development the soft tones may suffer. When the sensitising bath is free from chromic acid the tissue sensitised in it keeps much longer than if the slightest trace of it were present.—Eds., B.J.P.]

#### THE THEORY AND PRACTICE OF INTENSIFICATION.

To the Editors.

Gentlemen,—I am afraid Mr. Wall has put the most ambiguous construction on my statements regarding mercuric chloride intensification. Some of the largest granules of reduced silver bromide are unquestionably affected only on their outer surfaces, especially with insufficient bleaching, which latter is frequently purposely given to reduce contrasts in a negative.

As regards the plotting of the curves, I cannot enter into a dispute about them; they are not in all cases plotted from figures, but all tabulated from careful experiments, and in any case it would be ridiculous to publish false readings or results "specially discovered for the occasion." No one would gain anything, except the acrimonious critic.

With reference to uranium intensification, I quoted Otterberg's work quite correctly in saying that the compound precipitated

with an excess of uranium nitrate was  $(\text{UO}_2)_3, \text{K}_2(\text{FeCy})_6, 6\text{H}_2\text{O}$ . Otterberg states that the compound produced is brown, but red an excess of ferriyanide be present. This difference I certainly contradict, as if the bath containing the excess of ferriyanide allowed sufficient time to work, the colour of the negative *precisely the same* as when an excess of uranium nitrate is present. This is confirmed spectroscopically. I enclose two negatives of plates intensified with the two solutions recommended by Otterberg, and I leave the Editor to add a footnote as to whether one "brown" and the other "red"—both are reddish-brown. This has been verified over and over again, though the case might be altered if the conversion into ferrocyanide were carried on in test-tubes and not in the film.

Intensification reminds one of the saying: "Quot homines, sententiæ," and any articles on the subject could be contested by quoting contradictory "authorities," each and all of whom claim to be right.—Yours,

T. THORNE BAKER.

[We can go so far as to say that the slips are as described by our correspondent. Apparently the differences between Otterberg's work and Mr. Baker's require confirmation.—Eds., B.J.P.]

## Commercial & Legal Intelligence

**DISCHARGE of a Blackburn Bankrupt.**—Before his Honour Judge Hamilton, at the Blackburn County Court, on May 7, an application was made for discharge from bankruptcy by Mr. Harry Backhouse, solicitor, on behalf of Edwin Hargreaves, 16, Sarah Ellen Street, Blackburn. Applicant was a photographer, lately residing at Hawthorn Villa, Wilpshire, and carrying on business at Sudell Cross. The receiving order was made on September 9, 1903, and the first and final dividend of 4s. 1½d. was paid on proofs for £397 9s. 7d. His Honour granted the application.

**A LEICESTER Bankruptcy.**—The affairs of Arthur Weatherley, photographer, Gallowtree Gate, came before the Leicester Bankruptcy Court last week. Liabilities, £254 15s. 10d.; assets, £44. Mr. Bulman appeared for the debtor, who said he had been in business in Gallowtree Gate for about eighteen months or two years. He had been an operator at a photographer's in Leicester up to then. Debtor was cross-examined at length as to his books, but said he did not understand book-keeping, and could not explain them, as he had had no education. He traded as Weatherley and Co., Mr. F. J. Hill, his brother-in-law, being the Co., and an account was opened at the Capital and Counties Bank in their joint names. The examination was adjourned for the production of certain books, the Registrar saying that it was his view that inquiries should be made in the interests of the trade creditors how far Mr. Hill had made himself liable as a partner.

**BANKRUPTCY in Islington.**—The affairs of G. W. Austen, photographer, of 15, Highbury Place, Islington, N., came before the first meeting of the creditors on Friday last at the London Bankruptcy Court. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £629 15s., of which £505 15s. was due to unsecured creditors, to partly secured creditors £68 15s., the value of the securities being estimated at £60, thus leaving a balance of £8 15s. to rank against the estate for dividend, and making the total liabilities expected to rank amount to £514 10s. The assets were estimated to produce £119 7s. 6d., from which £55 5s. 11d. had to be deducted for the claims of preferential creditors payable in full, leaving the net assets at £64 1s. 7d., and disclosing a deficiency of £450 8s. 5d. It appeared that the debtor commenced business as a photographer sixteen years ago, with a free capital of about £600, and he had always personally superintended his business. After the official receiver had dealt with the proofs of debt lodged, he stated that he had received an offer of £126 12s. for the debtor's household effects and stock of negatives from one of debtor's friends. The official receiver's valuers had gone through the debtor's effects, and they advised the acceptance

offer. Mr. Sichel said he was in the photographic business, and did not think the negatives were worth anything to another photographer, although they might be of some value to the debtor, and that they had only the furniture to deal with, and under the circumstances he thought the offer was a very good one, and it should be accepted. A number of other creditors concurred with the offer. With regard to the appointment of a trustee the meeting decided to leave the estate in the hands of the official receiver, and the latter said that that being the case, he should accept the offer and distribute the assets among the creditors as quickly as possible. The meeting was then closed.

**QUESTION OF HALF-HOLIDAYS.**—The Derby Stereoscopic Company, 64, St. Peter's Street, were summoned for that on April 11 they were the occupiers of a certain workshop within the meaning of the Act, and having given notice of the substitution of Wednesday for Saturday, they did unlawfully employ certain young persons after 5 o'clock in the afternoon—till 5.45. Mr. H. Smith, His Majesty's Attorney General for Factories, prosecuted, and Mr. J. R. Pinder appeared for the defendant company. Mr. Smith explained that his assistant, Mr. Heald, had called at the place and found seven women and eight persons at work in the workshop mounting, spotting, and printing photographs. There was an abstract of the Act in the hands of the court, and a form substituting Wednesday for Saturday as a half-day. Mr. Smith added that the case had been brought partly because there seemed to be a general, but erroneous opinion in the town amongst shopkeepers of this kind that they can work their assistants in the factory on the half-holiday immediately preceding Good Friday, as they were giving the Friday and the following day holidays instead. But he would point out that the law did not permit that, for both Good Friday and Easter Monday were public holidays, and had to be given by law. Mr. Pinder, for the defence, asked the Bench to accept the defendants' assurance that the same thing would not occur again, and added that it had been done before. He took it that the Home Office did not wish to press the case unduly, and asked the Bench to say that justice would be done by dismissing the summons on payment of the costs. The Bench took this view of the case, and dismissed it on payment of the costs, and the case was closed.

## News and Notes.

**IRE IN ANSTRUTHER.**—A fire broke out in the photographic studio of Mr. J. S. Ireland last week. The studio was a wooden erection, with a corrugated iron roof, and before the fire was discovered the whole structure was in flames. The erection was insured for £30, and the cameras and other apparatus were all destroyed, resulting in a total loss of £300.

**THE SECTION FOR INORGANIC CHEMISTRY** at the International Congress of Applied Chemistry, held in Rome on May 5, F. Heller described some improvements which he has effected in the manufacture of glass, by means of which he is able to produce the finer quality of glass in tank furnaces instead of the more costly pot furnaces. The process consists chiefly in using three tank furnaces, each maintained at a definite temperature; the first for fusing the raw materials at about 1,400 deg. C., the second for clearing the charge at 1,200 deg. C., and the third for working purposes at 1,000 deg. C. Photographic glass is said to be produced cheaply by this process.

**MESSRS. NORTON AND GREGORY, LIMITED**, the well-known photographers and drawing-office stationers, of Castle Lane, Buckingham Gate, S.W., announce that the business hitherto carried on by Mr. H. G. Carpmal as managing partner of Messrs. Allott, Jones, and Notley, of Westminster, has been amalgamated with their own, and that Mr. Carpmal has joined the board of directors.

**KODAK, LIMITED**, have arranged at their Gallery, 59, Brompton Road, S.W., a second exhibition, comprising a series of Kodak pictures by H.M. Queen Alexandra, and a further selection of enlarged Kodak pictures by distinguished amateurs. The exhibition is one of great interest, for in addition to Her Majesty's exhibits, the pictures represent the work of a great number of people distinguished in the art, scientific, and literary world.

## Answers to Correspondents.

\* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*

\* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- A. Hunter, 28, Castle Street, Shrewsbury. Photograph of Roberts Playing Billiards at Shrewsbury, September 9, 1905.
- J. G. Craik, 119, High Street, Deal. Three Photographs of Church Parade, Royal Marines, Walmer.
- E. G. Gegg, 18, High Street, Evesham. Photograph of the Foundation Stone Laying of the New Wesleyan Chapel, Evesham.
- W. H. Dee, 310, King's Road, Reading, Barks. Photograph of the Reading Temperance Prize Band in Forbury Ruins, Reading.
- H. Colebrook, 5, Grosvenor Terrace, Sidcup, Kent. Three Photographs of "New Crusaders" Football Club with London Senior Cup.
- J. H. Greenwood, 23, Cliff Street, Colne. Photograph of Colne Football Club, Winners of the Lancashire Combination Cup and Junior Cup.
- H. B. Cooper, 13, Abbey Park Road, Leicester. Photograph of a Street View, Cottesmore. Photograph of a View known as Sheep Dyke, Cottesmore.

**IMPROVER.**—We know of none. We can only suggest postal lessons, of which you will find particulars in each issue of the "Journal."

**ELECTRIC LIGHTING.**—Would you kindly tell me what candle-power electric arc lamp would be necessary to take cabinet groups of three or four figures using portrait lens, rapid plates, and an exposure of five or six seconds?—L. L.

The term "candle-power" is almost meaningless unless qualified in some way. With open arcs the measured candle-power may be much greater in one direction than another owing to the crater of the arc being obscured by the other carbon. With enclosed arc lamps, where the arc is much longer, the candle-power in all directions is more uniform. Five or six seconds is an unnecessarily long exposure, and reference to the article on enclosed arc lamps, which we published in the B.J. for March 2, 1906, will show that with the smaller lamp shorter exposures can be given at a quite nominal cost for electric energy. We assume  $f/4$  or  $f/5$  and a plate of 200 H. and D.

**E. M. MUDGE (Elkhart, U.S.A.)**.—We cannot identify the map from your reference. Possibly the quotation is not from a recent issue. We can only say that if you can supply a more informing description, a firm such as Messrs. George Phillip, educational publishers, Fleet Street, E.C., could supply you.

**M. E.**—"Photolithography," by George Fritz, translated by E. J. Wall, 3s. 6d. You might also get Wilkinson's "Photo-Mechanical Processes" (5s.), which contains chapters on the subject.

**COPYING.**—As I have a number of coloured pictures to copy for lantern slides, could you inform me of any book dealing with the most suitable coloured screen, etc.?—P. M.

No. 41 of "The Photo-Miniature" on "Copying Methods." (6d.)

**ALBUMEN P.O.P.**—Would you kindly inform me of the most suitable developer for toning "albumen" paper to give a cold tone?

I have used that advocated in the "Year Book," which I find gives too red a tone.—SAMOHT.

We cannot find a "developer" for albumen paper in the "Almanac," to which we suppose you refer. Kindly state your query more definitely.

**RAFFAELI COLOURS.**—Would you kindly inform me through the columns of your estimable journal where I can obtain the "solid oil-colour pencils of Raffaelli" referred to on p. 244 of the B.J. issue, March 30 ult., also the price of same?—M. J. S.

They are sold by many artists' dealers in this country, and we should suppose in South Africa also. Any London photographic supply house could get them for you.

**ARC LIGHT FOR P.O.P. PRINTING.**—I believe I noticed in a recent number some information on P.O.P. printing by arc light, and also the description of a frame for holding printing frames in a circle round the arc. If you can inform me of the number the information appeared in, and also any further information or source from which it can be obtained, I shall be most grateful.—ENQUIRER.

The article appeared in the B.J. of March 2. The Westminster arc lamps are the ones referred to. You can get further particulars of these from the company at Victoria Road, Willesden Junction, London.

**RIGHT TO EXHIBIT PORTRAIT.**—Some little time ago I photographed a young lady for postcards; at the same time I took one for a specimen. I showed them the proofs, of which they approved, but when finished they refused to have them, as they said they were not like them. Can they make me take the specimen out of the window?—A. R. Cox.

Yes, they can; according to the ruling in the Crooke-Irving case, the copyright in all the portraits taken at a sitting belongs to those who paid for it. In the Boucas-Cooke case it was decided that when a sitter ordered a portrait to be taken he incurred a debt that was recoverable at law, and, therefore, the photographer had no copyright in it, and had consequently no right to use it for any purposes of his own. You can, of course, sue the lady for the debt she incurred, in the County Court. As a matter of policy, would it not be best to remove the portrait from the window, if there is an objection to its being shown, instead of giving offence to a customer?

**MAX.**—"Photo-Mechanical Processes," by W. T. Wilkinson. (Hampton and Co.) 5s.

**COLOURING BACKGROUND.**—Could you tell me if black lead, whitening, red lead, and thin glue or size are suitable materials to mix or use separately for painting a white lantern screen—for taking plain heads. Thanking you in anticipation.—E. G.

The pigments will do very well if you substitute for the black lead either lamp black or drop black. The mixture should be made warm, then allowed to get cold, and be applied in a jellied condition.

**COLOURING PHOTOGRAPHS.**—May I trouble you for advice re colouring glossy P.O.P. prints. I have painted some with ordinary water-colours, and they look very dull and patchy. 1. What can I do to restore the gloss on those already painted? 2. What should I mix with the colours to make them dry bright in future? 3. Would oil colours be better for the purpose? I do not like the aniline colours for the purpose—the prints are stereoscopic.—CHARLES MARSHALL.

1. The only thing is to go over the work with a brush charged with weak gum water. 2. Mix them with a weak solution of gum instead of plain water. 3. No; not for stereoscopic pictures. We suspect that you have been using very common water colours. The best kind should be employed for colouring photographs, such as are sold by the best makers.

**METOL HYDROQUINONE DEVELOPER.**—I make up the metol hydroquinone developer in somewhat large quantities, as I use it for plates and paper, but I cannot keep it in good condition more than a few days. The usual ways of mixing seem to be three: 1. In one solution. This at the best only keeps a few days; but if the metol and hydroquinone are not first quite dissolved before adding the sodas, the whole at once turns black. 2. Carbonate of soda in No. 1, metol, hydroquinone, bromide potassium, and sulphite soda in No. 2: with this way of mixing No. 2 turns

into a white curd in about an hour. 3. Sodas in No. 1, metol, etc., in No. 2; No. 2 discolours about second day.—E. G.

The trouble of discolouration is entirely due to the use of little sulphite, and the white curds are a chemical combination of metol and hydroquinone caused by the solution being strong. If our correspondent will use the following for and make it as advised, he will be able to keep it at six months: Dissolve 35 grains of metol in 5oz. of distilled water, add 2oz. of sodium sulphite and 10oz. of distilled water, then add 1½oz. of sodium carbonate and 50 grains of hydroquinone, and enough distilled water to make 20oz. in all. A perfectly clear and colourless solution will be obtained. He can, of course, vary the proportion of metol and hydroquinone, but the method of making will remain the same.

**D. L. MURDOCH.**—We should expect the alum to act on the plates slightly, but not sufficiently to affect the pigments.

**COLOUR PHOTOGRAPHS.**—1. Is there any book published on tricolour photography? 2. Can the plates be obtained ready prepared? 3. Is there any other process more direct to get photographs of colours than the above?—AMBITIOUS.

1. "Colour Photography," by Bolas, Tallent, and Senior, published by Marion; "Three-Colour Photography," by Baron von Hübl, published by Penrose and Co. 2. Certainly they can. 3. The three-colour principle is practically the only one which is available, though a three-colour process need not involve the taking of three separate negatives. You had better refer to the review of the recent exhibition of colour photography at these offices, which appeared in our issue January 26. 4. There is nothing in the process beyond the species of hand-colouring—at least that is our conception.

**RETOUCHING.**—Should you consider it correct in retouching a negative to turn it round at different angles to get certain strokes conveniently, or should the negative be kept in an upright position on the desk until finished? Which do you think real first-class retouchers do.—F. F.

Although some retouchers of experience make a habit of turning a negative at different angles when retouching, in order to more conveniently apply the strokes, it is a very inexpedient practice, and, unless the retoucher is very skillful, is highly inimical to the retention of the likeness. Indeed, so many employers are very keen against the practice, and we once knew of a case where the employer summarily dismissed his retoucher for so doing. A really clever retoucher not only finds the practice unnecessary, but obtains better and more truthful work without it.

**C. AND A.**—We think you might apply to Rajar, Limited, Mobberley, Cheshire.

**G. M. MASON.**—(1) We are afraid it is impossible to give you a rule which would not be misleading. A fairly good rule for such cases is the following:—Stop down the lens, after focusing, until you first begin to lose sight of detail in the details. At this aperture the exposure with a plate of the "rapid" class will be about eight or nine minutes. (2) Most probably there is no copyright existing, and therefore you would not be infringing.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

an exhibition of photographs by R. Dührkoop, now opened at offices, closes to-morrow (Saturday) at 12.30.

photographers in Rochester (New York State) have combined to d profitable rates for photographing schools and clubs. (P. 410.)

re methods of attracting business are communicated by American photographers in conference. Their suggestions include book-baby shows, and show-case inducements. (P. 408.)

od printing, like good-looking clothes, creates a favourable sion. (P. 410.)

ention is drawn by the “Lancet” to the greater pains taken e Continent in photographing the dead. (P. 409.)

ors’ Photographs.—The full text of the suggestions of the s’ Association is given on page 410.

our-Photography.—An article by Mr. A. J. Newton, dealing the requirements for printing from sets of three-colour nega- gives the ideal curves which pigments should have for print- from negatives made through a given set of filters. The rements of some actual pigments are appended. (P. 406.)

Neuhaus is said to have made further improvements in the h-out process of colour printing. (P. 403.)

series of systematic chemical tests for the examination of paper ded for packing photographic materials or for the support of graphic emulsions are given on page 404.

properties of plates and filters in orthochromatic work occupied roydon Camera Club last week, when Mr. C. E. K. Mees was ectrurer. (P. 415.)

ets impregnated with developer have been patented. Other ts of the week relate to cinematographs, copying machines, ras, and pneumatic printing frames. (P. 411.)

## EX CATHEDRA.

### The Metric System.

Quite recently our Post Office authorities announced that in future letters for France and Germany up to the weight of 15 grammes would be allowed to pass for one penny. In this concession, advocates for the adoption of the metric system in this country have seen cause to assume that their wishes were about to be realised, whereas it should be obvious that the new arrangement is simply a matter of accommodation between British and foreign postal authorities. The British limit of weight was previously half an ounce, though 15 grammes (which is a little over half an ounce) was the limit in the foreign countries, hence a little over half an ounce and under 15 grammes was over weight and liable to a sur-charge in this country, though under weight in, say, France. This anomaly has been removed by the new arrangement, which is very much to our advantage, but involves no concession to the principles of the metric system at all. On the contrary, the recent proceedings at the Postal Congress, as reported in the English Press, should convince even the most ardent metrical enthusiasts that their ambition is farther from realisation than ever, for, according to the “Globe,” of April 30th, the protest of the English representative against the adoption of the metric system was supported, not only by such non-metric countries as the United States, Turkey, and Japan, but by the metric countries, France, Spain, Belgium, and Italy. This is a very significant fact, for France is the birthplace of the metric system.

\* \* \*

### Natural and Arbitrary Standards.

The reasons for the metric system not being universally popular, even in the countries that have officially adopted it, are fairly obvious. The system is too primitively simple and too inadequate to fit the requirements of all trades and professions, and so long as the system recognises decimal subdivisions only, confusion is sure to exist owing to the retention of older and more convenient units and the unauthorised introduction of new ones. The original pure metric system contained many units of no value whatever, that are never used and almost forgotten, but it included no unit of length corresponding to the indispensable chain, and no unit of weight corresponding to the universal pound. As a natural result these deficiencies have been remedied by illegal methods. Binary subdivisions are necessary, while the undying popularity of the dozen and the gross also shows that duodecimal subdivisions cannot be ignored. The attempt to supersede all non-decimal systems by one that is purely decimal is bound to fail. Yet the fact cannot be disregarded that the metric system in the definiteness of its units of volume, mass, and length, and in

the simple relations which these bear to one another possess claims to universality which deserve to be recognised, even though the Parisian buys his wine by the quarter litre.

\* \* \*

### Photography in Municipal Advertising.

The Corporation of Cardiff are inviting photographs from local professionals and amateurs for ten views of Cardiff for use as advertising. A first prize of five guineas and a second one of three guineas is offered for the two best sets, sums which should gratify the Cardiff ratepayers by their moderation rather than create an inflated idea of the advertising value of photographs in the public mind. Half a guinea for a photograph to be employed in advertising is not a large sum, but the municipal offer is one which will perhaps suggest to photographers in other places the possibility of discovering business for themselves in this direction.

\* \* \*

### Actors' Photographs.

We publish in another column the proposals laid before the Professional Photographers' Association by the recent deputation from the Actors' Association. It will be seen that the actors are anxious to exercise control over the photographs of themselves which are issued to the public, either in newspapers and magazines, or as postcards, and to share in the profits which may attend these forms of distribution of their portraits. Nobody will blame them for taking any steps which seem right to them to secure these desirable consummations, though we can hardly suppose that they will meet with much success in endeavouring to get the P.P.A. to be an arbitrator between them and the theatrical managers. Questions as to the payment of actors to attend a photograph call should be discussed with the managers, and as for the other restrictions which the actors seek to put on the use of copyright photographs of themselves, it is impossible to lay down a general line of action. Each case, it seems to us, is one for agreement between the photographer and his theatrical sitter. Good photographs of an actor, as the deputation pointed out, are very valuable to the actor, and the right to grant reproductions of them may be very valuable to the photographer. The conditions under which use shall be made of such photographs should be capable of arrangement between the interested parties, or an actor may obtain the sole rights in the photograph by paying the photographer. This latter course does not seem to have appealed very strongly to the actors.

### Modern Physical Chemistry.

Last week we had a note on the experiments recently published by Prof. Louis Kahlenburg, and suggested that it was highly desirable that his results should either be affirmed or disproved as soon as possible. According to the report in "Nature" of May 3, these results, if verified, would destroy the basis of the theory of electrolytic dissociation, but this doleful prophecy is pretty effectually disposed of in "Nature" for May 17, by Mr. W. C. D. Whetham, F.R.S., who points out that "the theory of ionic dissociation rests upon electrical evidence, and by such evidence it must be tried." He explains that the fundamental theories of physical chemistry are altogether independent of any assumptions as to the nature of osmotic pressure, which may be due to some as yet undiscovered cause. The theory by van't Hoff, which applies the gas law to dilute solutions, is not based on experimental observations of osmotic pressure. It is simply confirmed by them when they are conducted under certain rigid conditions which van't Hoff postulated, and the fact that the theory is not

fulfilled under *wrong* experimental conditions is obviously no argument against it, especially considering that it has been proved by Professor Larmor and others in various different ways. Mr. Whetham remarks that the basis of the van't Hoff theory is sometimes misunderstood. It is so evidently the case that his clear exposition of it together with his explanation of the true basis of the theories of ionic dissociation, are both very welcome. Prof. Kahlenburg's experiments will probably afford handy weapons to the opponents of the theories of physical chemistry, but they will have to be cautious how they use them, for it is evident that his attack has been aimed at the wrong place. Mr. Whetham does not depreciate the value of these new experiments. He considers them important and interesting, though from a somewhat different point of view from that taken by Prof. Kahlenburg. The Earl of Berkeley and Mr. E. S. T. Hartley, however, attack one of the experiments to show that it is valueless. Very possibly there will be further discussion of considerable interest.

\* \* \*

### Post-Mortem Photography.

It will be remembered that, a few weeks ago we made some comments on the remarks of a London coroner on the little value of many photographs taken after death, saying that they were frequently not taken in an intelligent way. It is clear that these remarks do not apply in all cases. For example, at an inquest held last week at Swansea, on the body of a woman alleged to have been murdered by strangulation, in his evidence, the doctor, Dr. Urban Marshall, senior house surgeon at the Swansea Hospital, produced photographs that distinctly showed all the finger marks on the throat of the deceased. The coroner complimented the witness on producing such excellent photographs of the face of the deceased, and added that it ought always to be done in such cases. Evidently these photographs were taken in an intelligent way, and should be valuable evidence in the Court at which the prisoner will eventually be tried. It is not stated whether the photographs were taken by the doctor himself, or by someone else under his supervision, but evidently they fulfilled the object in view. It would be well in all cases where the death is supposed to be caused by violence that the photographs should be taken under the supervision of a medical man, who would arrange the body so as to ensure the most essential parts being shown, instead of its being left to the mortuary keeper at the photographer. Post-mortem photography, as Mr. Lang Sims recently pointed out in our columns, is by no means pleasant work, yet it is obvious that it should be well done and under the most favourable conditions the circumstances will allow. We reprint in another column an article from the "Lancet," showing the attention the subject receives on the Continent.

\* \* \*

### Lantern Apparatus.

The lantern season being now at an end, it may not be out of place to offer one or two hints on storage, particularly of those furnished with oil lamps. The old wicks should be taken out and thrown away, as they will be useless. The wick tubes should be cleansed by brushing them out with clean paraffine oil, or with benzoline. The stale oil should be drained off and the reservoir rinsed out with fresh. The outside of the reservoir should be well cleansed with benzoline, and when this has been done all the parts should be put out in the sun for a few hours, when all traces of the oil will disappear. The lamp may then be put away, with the certainty that when next required for use it will be equal to a quite new lamp. Without this precaution the stale oil will harden on the outside of the

reservoir and in the wick tubes, and be difficult of removal. When the lamp is lighted in some months' time it will well—"stink the house out." The adage, "A stitch in time," etc., applies with especial force to lantern lamps that have to lie out of use for several months.

**Extraordinarily Old Engravings.** Last week we commented on the recent great slump in the pictures by modern masters, and quoted the exceedingly low prices realised at Christie's auction the week before. It will be interesting now to state some of the prices that some old engravings made at the same auction rooms one day last week. For instance, the impression of J. Walker's plate of Mrs. Musters, by Romney, made no less than £430, a great contrast to F. Goodhall's, R.A., well-known painting, "Raising the Maypole," which in 1873 made 1,470 gs., and sold the week before last for no more than 400 gs. An impression of the bistour of Morland's "Delhi in Town," by J. R. Smith, realised £130. A set of Wheatley's "Cries of London" fetched no less a sum than £680; £201 were paid for a close-cut print of "Mary Duchess of Lancaster," by Mr. Ardell, after Hudson. Hoppner's "Elizabeth of Mexico," in colours, by W. Ward, made £183; and £183 were given for C. Turner's "Le Basier," after Greuze. Other very high prices were realised for old engravings. When we mention that the prices for the prints were paid by dealers, probably to sell again, or possibly bought on commission, it is able to realise the present market value of old prints the best engravers, as compared with paintings by modern artists.

**Factory and Photographers.** A case of interest to photographers whose workshops come within the Factory Acts was reported in our issue last week. We call special attention to the case here as we know of others where the Act has been continually infringed in the London district under similar instances. In the case referred to a photographic party at Derby (occupiers of a certain workshop within the meaning of the Act) had given notice of the sub-letting of Wednesday for Saturday for the half-holiday, and had employed certain young persons after the regulation time on Wednesday. For the defendants it was claimed that, as the Good Friday and the Easter Monday Holiday followed the Wednesday, they were under no impression that they could keep the hands employed on the half-day on the Wednesday. The factory inspector for the district, who prosecuted, mentioned that the case had been brought particularly because there seemed to be a general, though erroneous, idea in the town amongst employers of this kind that they can employ the assistants in the factory on the half-holiday immediately preceding a Good Friday, as they were giving the Friday the following Monday as holidays instead. He pointed out that the law did not allow that, as both Good Friday and Easter Monday were statutory holidays, and had to be given by law. The defendants' advocate assured them that the law had been infringed through ignorance, and that the occurrence would not take place again, and that the summons might be dismissed on payment of costs. The Bench took this view of the case, and assessed it on the payment of £2 8s. costs. We have, as we have just said, called particular attention to this case as many photographers whose workrooms come under the Factory Acts are ignorant of the law on the subject.

They must remember that it is illegal to employ their work-people on the half-holiday preceding or following a Bank Holiday.

#### The Bleach-out Process.

According to Dr. Donath, whose work we review elsewhere, Dr. Neuhauss has made some slight changes in his method of working the above process, and as we gather that the author had the advantage of special information direct, it probably represents the very latest advance, though Neuhauss himself has not yet made any announcement. The particular modification is in the fixing bath. Hitherto a weak solution of sulphate of copper has been used, but now it is advised to immerse the plate or paper, after washing, in a 10 per cent. solution of tannin and acetate of soda for fifteen minutes, then rinse and bathe in a saturated solution of tartar emetic, again rinse, and transfer to a saturated solution of lead acetate. It is obvious that by this treatment the dyes would be converted into pigment or lake colours, and should therefore possess a greater stability to light. The treatment being practically that suggested by Hazura in 1898 for obtaining printing ink pigments from the coal-tar dyes. A large number of these were examined by Valenta (Beiträge zur Photochemie und Spectralanalyse), who finds that auramine and methylene blue give very stable pigments, whilst the erythro-sines and eosines are much less stable.

#### The Eye and the Camera.

Much energy has been expended, and not a little wasted, on comparing the eye with the camera. Such comparisons are usually misleading, for the differences between the two optical systems are both more striking and more important than the points of agreement. At the recent Chemists' Exhibition we saw a new model of the "Schematic Eye," designed by Messrs. S. D. Chalmers and H. S. Rylands, which very aptly illustrates the limited extent to which the eye corresponds with a camera. This model is practically a small camera with a ground glass retina resembling the actual retina in form, and a lens that closely represents the total refractive power of the eye when the space between the lens and retina is filled with water. By racking the lens in or out certain of the effects of myopia or hypermetropia (short sight or long sight) can be reproduced, while those of astigmatism can also be represented by substituting a toric lens (one side spherical and one cylindrical) for the simple spherical lens. This model eye seems to have been designed for students wishing to practice elementary skiascopy, ophthalmoscopy and opthalmometry, and for such a purpose it will no doubt be useful, though no model can supersede the living eye with students who will ultimately have to practise on actual patients. As a clever and apt illustration of the points of resemblance between the eye and the camera, it is, however, of considerable photographic interest, and lecturers proposing to deal with this subject would find one of these models to be of considerable illustrative value on the lecture table.

#### The Projected Poisons and Pharmacy Act. The Government Beaten.

A Bill is before the House of Lords, introduced by the Lord President, Earl Crewe, to amend the present Pharmacy Act. It is entitled "An Act to regulate the sale of certain poisonous substances and to amend the Pharmacy Acts." Framed under the auspices of the Pharmaceutical Society, the Bill is in the interests of pharmaceutical chemists. One of its chief

objects seems to be to prevent companies and firms having many shops styling themselves chemists, or chemists and druggists, although they have duly qualified chemists to manage them. An amendment to the clause dealing with this matter was proposed last week by Lord Ebury, who supported the preservation of companies' licences on the ground that the clause, if carried, would seriously injure a large number of firms which had, at any rate, benefited the public by giving them cheap drugs. The Lord President offered to allow seven years to elapse before the companies should be deprived of their titles, but on Lord Ebury's amendment being put, it was carried by a majority of 6. It is difficult to see why companies, or firms, having several shops should not style themselves chemists, provided they have a duly qualified manager for each shop. Under the existing Act it is lawful for any executor, administrator, or trustee to the estate of a pharmaceutical chemist to continue the business, provided it is conducted by a duly qualified assistant. It seems only reasonable that a similar privilege should be granted to companies. In the new Bill there are additions to the schedule of poisons, but none that will effect photographers, except, perhaps, preparations of corrosive sublimate (bichloride of mercury). In the existing schedule only corrosive sublimate is mentioned, and not preparations of it. Mercuric iodide and mercuric sulphocyanide are in the new schedule, but they are but of little moment to photographers.

#### NOTES ON THE CHEMICAL TESTING OF PAPER FOR PHOTOGRAPHIC PURPOSES.

HAVING had occasion recently to test some paper with regard to its suitability for packing photographic plates, it appeared possible that a few notes on the chemical examination of paper for substances harmful to the photographic film might be of interest. They are, of course, to be taken as suggestive rather than complete. First, as to the paper itself, it is practically essential that a paper which is to be in contact with a silver haloid film—whether as a basis or in packing—should be made from rag or esparto and not from wood-pulp. The microscopic and chemical methods for identifying wood-fibre in paper have been dealt with in an interesting article in this journal,\* but some supplementary tests are given on account of the importance of the question. Wood-fibre and the ligno-celluloses generally belong to the so-called compound celluloses, which are distinguished by a much greater reactivity from the typical cellulose group, and thereby rendered in many ways less valuable. Beside the reactions (1) with phloroglucinol, which stains ligno-cellulose deep magenta, and (2) Schulze's iodine solution, staining cellulose blue, but wood-fibre brown, other characteristic reactions are (3) chlorination (chlorine water), followed by sodium sulphite solution, which gives a deep magenta coloration, (4) treatment with ferric ferricyanide, the red solution obtained by mixing in equivalent proportions solutions of ferric chloride and potassium ferricyanide. The fibre-substance rapidly decomposes this body to Prussian blue, which is copiously deposited in the fibre. If the paper be sized, this very characteristic reaction may be obscured by the presence of gelatine, which also decomposes the ferric ferricyanide, but the precipitate in this case is of a greenish colour, only darkening to blue on standing.

The quantitative estimation of the components cannot be dealt with here. Those interested should refer to standard text-book or the monograph of Cross and Bevan on "Cellulose."† But one fairly simple method of determining the presence and proportion of wood-fibre is so pertinent to the matter in hand that it demands brief mention. Wood-fibre and the ligno-celluloses generally have the property of taking up atmospheric oxygen and fixing it in the form of a peroxide, giving the reactions of the typical *hydrogen peroxide*. One of these is the oxidation of the methyl derivatives of para-phenylene diamine to resorcinol, a reaction which is used in the detection of colouring matters, and this has been applied by Wurster to the formation of an approximately quantitative method for determining the amount of wood-pulp in paper. A "test" or indicator paper is prepared by incorporating a definite quantity of the reagent mentioned with a pure cellulose paper; this indicator paper is pressed into a moistened portion of the paper under examination. The depth of colour produced is compared with the tints of a scale of standard coloured papers, when the percentage of wood in the paper corresponds to the depth of coloration in the test paper, the oxidising effects corresponding to a colour being also expressed in terms of normal iodine solution.

It is this formation of unstable peroxides which is responsible for the colour changes of wood-pulp paper mentioned by Mr. Pigg as occurring when they are exposed to light and moisture, and which render them so objectionable as a basis for photographic or other picture-making. But also, and bearing more directly on the main purpose of these notes, it is to this action that the deleterious effects of papers and woods on sensitive films are due. The researches of Dr. W. J. Russell on the fogging action of various woods will be remembered, one important point being the increased effect with light-exposed or "insolated" woods. In natural woods the effect is complicated by the presence of resins and turpentine oils.

Beside this primary objection to wood-pulp in paper which justifies the stress laid on its detection and estimation, we have next to consider the detection of foreign substances more or less accidentally introduced into the paper in (a) the process of manufacture, (b) storing and handling, (c) sizing or loading.

The substances which are capable of producing a developable impression or "fog" on sensitive films are so numerous that it were almost easier to name those which do not fog the film than those which do. The subject has, however, been dealt with in detail at various times in these columns, and a large number of substances are by no means likely to occur in papers. In dealing with the detection of these substances by chemical methods it must be remembered that their photographic effect is cumulative over long periods, and therefore surpasses in sensitiveness the most delicate chemical tests. The chemical analysis, especially when made for a considerable quantity of the paper, is a court giving a good preliminary judgment, but long contact with the photographic film may overthrow its decision. The following scheme does not pretend to be systematic or complete, but indicates the principal tests of value.

*Preliminary.*—It is supposed that an examination of the paper in the manner sketched above has decided the presence or absence of wood-pulp. If this be present, and also if the paper be sized with gelatine, these may confuse the results of some of the tests, but the necessary deviation will be mentioned in its place. In most cases it is desirable to use a considerable quantity of the paper, and extracts should be made by successive digestion with the same portion of solvent to obtain concentration. A valuable control for several of the tests is obtained by

\* "Brit. Journ. of Phot." 1904, 51, 634 (July 15).

† Lowmans, Green & Co.

jecting a pure cellulose paper such as analytical filter-paper to the same treatment as the paper under examination, and comparing the results.

After noting the acid or alkaline reaction of the paper, marked deviation from neutrality being unfavourable, may examine for:—

**Reducing Substances.**—The paper is soaked in separate solutions of auric chloride and ammoniacal silver nitrate, and warmed. If the paper is free from gelatine or wood-fibre there should be but very slight or no reduction in an hour. Gelatine produces a purple precipitate of gold, and in this case the modification is (a) to test the stannous extract obtained by prolonged and successive extraction with cold distilled water, (b) to remove the stannine with hot water and test the residue. Any strong reduction with these reagents compared with the control would lead to a separate examination for possible reducing agents. Stannous salts are the only likely bodies beside metals, which are dealt with later.

**Oxidising Substances.**—The preliminary examination should have indicated the presence of wood-pulp and any oxide from this. The behaviour of the paper compared with the control should be tested with extract of permanganate, or amido solution. The most likely oxidising substances are ozone and hydrogen peroxide, which are eliminated together in the following test. If these are not found, but the paper still has a strong oxidising action, a special analysis may be made.

**Hydrogen peroxide.**—The well-known fogging action of this substance has been investigated by Dr. Russell and others, and probably when the time is extended is more sensitive than ordinary chemical tests. The best characteristic tests are:—(a) The paraphenylenediamine reaction already mentioned; if this occurs when other tests show no wood-fibre is absent, then the peroxide is present as an impurity. (b) The paper is soaked in potassium bichromate acidified with sulphuric acid, and then treated with ether; the paper may be extracted with ether and chromic acid added. A bright blue colouration denotes peroxide, but the ether must be taken to use pure ether from a well-filled bottle and add chromic acid to a separate portion, as ether contains the presence of air and light forms a peroxide itself, giving the foregoing reaction. (c) The most sensitive test is to treat the paper with 1 per cent. vanadic or titanous acid. The former gives with peroxide a red brown precipitate, the latter a yellow one. The best way is to more or less pulp the paper, digest with water in the cold, and concentrate the extract by evaporation. Vanadic acid gives a red colouration with .005 grain of peroxide in 100 c.c. of extract and Otsuki claim to have detected peroxide with vanadic acid whenever the former produced a photographic fog.

**Traces of Organic Substances.**—The harmful substances are: (a) Turpentine oils. (b) Ether, methyl alcohol, and formaldehyde. (c) Acetic and formic acids. There is not much likelihood of these bodies being present, but the presence of peroxide being determined, they may all be eliminated as follows:—The pulped paper is extracted with acetone or ethyl alcohol, neither of which when pure has any effect on the photographic film. The extract may then be applied to a sensitive film for as long as is convenient (quite small traces by concentration will give an effect in 10 hours), and the results on development compared with a control plate in the pure solvent. A further test is to "activate" the extract by agitation with nickel powder for some hours and then test the filtrate as before. **Ammonia and Sulphur or Sulphides.**—The most delicate test for ammonia is Nessler's reagent, a solution of mercuric iodide in potassium iodide, rendered alkaline with

caustic potash. Very slight traces of ammonia produce a yellowish colouration.

Sulphides will already be indicated by the use of silver nitrate. Sulphur may be converted to a sulphide, and sulphide in traces revealed by sodium nitro-prusside, which in alkaline solution gives a violet colouration with the sulphide ion.

**6. Metals.**—It is well known that numerous metals in the free state and in alloys fog the photographic film even at a slight distance from it. The metals more or less active in this manner are magnesium, aluminium, zinc, cadmium, iron, cobalt, nickel, lead, bismuth, antimony, tin, and mercury. If these are in contact with the film or incorporated in the emulsion the effect is so much the greater. Small metal particles may get into the paper (a) in the pulping and other processes by attrition, (b) in the loading or surfacing with baryta. Baekeland has discussed the ill effects on photographic papers arising from these particles, and strongly recommends that all barium sulphate which is to be used for photographic paper manufacture should be treated with dilute sulphuric acid and then washed. Unfortunately these particles are likely to be locally distributed, and a particular test may not reveal them; coating the paper with a haloid emulsion and subsequent development will give black specks with a white surround, but this is a cumbersome procedure. Where any type-metal or other alloy or amalgam is founded, metallic vapours may be absorbed by the paper. A large quantity of this may be extracted with hot dilute nitric acid, and the metals tested for in the wet way. But a more general test is to compare the behaviour of the paper soaked in dilute hydrogen peroxide, with a control filter paper similarly treated. The strips are treated at intervals by the paraphenylenediamine method outlined above; an increased decomposition of the peroxide will be observed in the paper containing any finely divided metals.

Finally, radio-active bodies in extremely small amounts will, of course, produce fog; radio-activity, if suspected, should be tested for by the electrometer method, the gold leaf electroscope being capable of rapid and even quantitative determinations.

The foregoing notes are necessarily of quite a sketchy nature, but are put forward in view of the importance of the question to both the manufacturer and the user of sensitive films. In considering the suitability of a paper, the restrictions as to purity are more or less stringent according as the paper is required as a substratum of the sensitive emulsion, for packing in contact with the film, or for outside packing. General conditions of storage for films and papers are obviously suggested by the foregoing, and need no comment.

**A GOERZ BEQUEST.**—We see in the German papers that Herr C. P. Goerz, at the recent annual general meeting of his firm, has set aside 100 shares, of the nominal value of £5,000, but worth £10,000 at the present market quotation, for the benefit of employees who, according to the duration of their service, draw bonuses to the amount of about 10 per cent. of the net profits.

An exhibition of the work of Mr. Arthur Marshall, A.R.I.B.A., has been held for the past ten days in the Shepherd's Fine Art Gallery, Nottingham. Among the photographs is a Pompeian study, which possesses a special interest in that it was the only plate that Mr. Marshall was able to save from destruction by the sulphur fumes during his experiences in the vicinity of Vesuvius at the time of the recent eruption.

THE Royal Photographic Society has been invited to send collections of representative British pictorial and scientific photographs to the Berlin Universal Exhibition and to the New Zealand International Exhibition. The following committee has been appointed to invite exhibits:—Major-General J. Waterhouse, I.A., Mr. J. C. S. Mummery, and Mr. B. Gay Wilkinson.

## PIGMENTS FOR THREE - COLOUR PROCESSES.

It would appear that those asking for, and even those supplying, certain colours for use in three-colour printing, either as dyes for films, carbon tissues or printing inks, do not always clearly understand why these pigments are a blue, red, and yellow, and what particular hue such yellow, red, and blue should be.

The aim of three-colour photography is to reproduce automatically or mechanically the colours of the subject photographed, and without entering into any elaborate theory it is perhaps desirable to explain how it is that photography can do this. White light is composite, and is made up of an infinite number of pure colours, ranging from deep red, through red, orange, yellow, and blue. This is proved when we split up a narrow beam of light by passing it through a prism, which analyses it into its various pure colours, and this band of colours is known as the spectrum.

Now, it has been found by experiment that white can be reconstituted by taking a certain red, a certain green, and a certain blue-violet. On mixing these lights in equal proportions they will give white or greys according to their brilliance, and any other colour can be imitated by taking various proportions of them. As, for example, the mixture of red and green light will make yellow, the mixture of green and blue-violet will make blue. If no light is present there will be black; gradual addition in equal proportions of these three will give greys; as the equal amounts increase the greys will become lighter, until at last we have white.

Now, this fact is applied to making a photographic record of any coloured subject. Three photographs are taken, one recording the red light reflected, another recording the green, and a third the blue-violet. Suitably sensitive plates are required to record these three kinds of light, but they do not yet exist by themselves. Colour sensitive plates are obtainable, but not sensitive only to the particular regions of the spectrum required, so in practice means must be taken to prevent light other than that required to be recorded from reaching the plate, and this is done by means of a colour-filter somewhere between the object photographed and the sensitive plate. The nature of these filters will vary according to the character of the sensitive surface. Usually, however, the filters are red, green, and blue-violet. The point to remember is that the combination of plate and filter must allow only the desired light to be recorded.

### Negative Colour-records.

These three records will be negative; that is to say, the light reflected is represented by deposits of black metallic silver, and the absence of light is indicated by lesser deposits of silver, or none at all. The picture can now be reconstituted by means of projecting the three coloured lights, the method known as additive synthesis. To do this glass positives (transparencies) are made in which the red, green, or blue-violet light recorded will be shown by the greater or less transparency of the positive, and if these lights are projected through and superposed the picture will be reconstituted on the screen with great approach to truthfulness. Usually the work cannot be reproduced by means of coloured light, from the obvious difficulties in the way, so that another method must be used, that of absorbent pigments, which is known as subtractive synthesis.

### Subtractive Synthesis.

The same principle is involved as in the first method, only in this case the white light is reflected from the white paper on which the reproduction is made. If we assume this white light also to be composed of red, green, and blue-violet,

then if we place on it a pigment which will absorb the blue, as, for example, a yellow, another pigment which will absorb the green, as a magenta, and a pigment which will absorb the red, as a green-blue, then if these pigments are applied in full strength all the light reflected from the paper will be absorbed, and the result will be black, or if applied in lesser amounts grey. If these pigments are of correct hues, they together will produce either a blue-violet (that is, the magenta and green-blue), a green (that is, the yellow and green-blue), or a red (that is, the magenta and the yellow), and mixtures of some or all of them in varying proportions will reproduce almost any tint; this is in practice what they do give in so far as the pigments available approximate to the correct absorptions. From the above it follows that hues of the colours having correct absorptions must be complementary to the light recorded. Just as an ordinary negative of a black and white subject records the white reflected and prints that which was not recorded, minus white, that is black, so each of the three records are printed in their complementary minus colours, pigments, which in the absence of any record on either of the three-colour negatives will all be printed, and so give black, while the presence of some record in equal amounts on the three negatives would mean a corresponding absence of the absorbing pigments, which would result in a grey, more or less approaching white, and similarly for every colour according to the amount of the absorbing pigments printed to correspond to the colour recorded on the negatives. Therefore we can know what light should be recorded, and in order to get a clear and definite idea of this resort must be had to the spectrum, the diagrammatic representation of which by means of a parallelogram may give sufficient indication of a spectrum extending from 4,000 A.U., the first visible violet, to 7,000 A.U., the last visible red.

### Relation of Printing Colour to Light Filter

Now, if we photograph the spectrum and assume the red necessary to be recorded to be those arrived at after our experiments at the L.C.C. School of Photo-engraving in Lithography, an account of which is given in detail in the *Journal of the Royal Photographic Society*, October, 1905, then the blue record should give a negative having a silver deposit from 4,000 to 5,000 A.U., shaded in diagram, v.

from 5,000 to 7,000 will not be recorded on the plate, therefore this will constitute the shadows. If we mix together all the colours comprised between 5,000 and 7,000 A.U. will give the hue that the complementary or minus pigment should have. If a perfect pigment of this hue is placed on anything reflecting white light, it will be found to be a particular shade of yellow, because it absorbs all the blue which was reflected from the white surface, while it transmits all the remaining colours of the spectrum, and the mixture of these remaining colours is of a yellow hue. That if our blue record extends from 4,000 to 5,000 A.U., our ideal printing colour will be such that if analysed spectroscopically it will be found to absorb all the blue recorded, and to be perfectly transparent to all the colours not recorded, viz., from 5,000 to 7,000 A.U. Naturally, an ideal is not absolutely attainable, but it could probably

approached more closely than at present, if due regard were always had to theoretical requirements.

The green negative should record from 4,600 to 6,000 A.U.,

therefore the printing ink should be that colour given by a mixture of the lights not recorded, viz., from 4,000 to 6,000 A.U. and 6,000 to 7,000 A.U., such a coloured pigment, ideal, being one that, when placed above white, would absorb all the colours recorded and be perfectly transparent to all the colours not recorded.

The red negative should record from 5,800 to 7,000 A.U.

therefore the printing ink should be that colour given by the mixture of lights not recorded, viz., from 4,000 to 5,800, such a coloured pigment, if ideal, being one that, when placed above white, would absorb all the colours recorded and be perfectly transparent to all the colours not recorded.

In order to examine the properties of commercial colours for three-colour printing, I recently selected several sets supplied for different purposes. The results and the method of examination are detailed below. The four sets of colours examined are as follows:—

1. and 2, carbon tissues; shown 0000 and xxxxx.

3. Dyes for three-colour printing by imbibition; shown

4. Printing inks for half-tone block work; shown ————. In the various charts the ideal printing colours are shown by the thick black line

The easiest method of ascertaining accurately how nearly perfect are the colours intended to be used is by measurement with a spectrophotometer, and four sets are given here from amongst several kindly measured for the writer by Mr. Kenneth Smith. The measurement consists in producing two spectra, side by side, one from a white surface—for example, the paper on which the pigment is intended to be spread—the other spectrum reflected from the pigment after being put in position on part of the same surface. The spectra are compared in small strips for every 100 A.U., the lighter one—viz., the one reflected from the white surface—being cut down by crossed Nicol prisms until it exactly matches the spectrum reflected from the pigment itself. The amount by which the white spectrum has to be cut down represents the amount of absorption, and can be shown graphically by a curve, the ordinates of which represent percentages of the light reflected, that which is not absorbed being absorbed; the abscissæ represent the wave length of the spectrum. The angle at which the pigment is viewed is adjusted so that the surface reflection is at a minimum.

Considering these pigments separately, it will be seen that the yellows (fig. 1) approach nearest to ideal requirements. But all of these absorb too much of all colours, absorbing about twelve (12) per cent. of the pure colour of which they reflect most. They absorb a very great deal of the yellow-green and green that they should reflect entirely, and they reflect only two to nine per cent. of the blue and violet that they should completely absorb.

In the case of the reds (fig. 2), the curves show that their absorption is greater, varying from twenty-five (25) per cent. to forty (40) per cent. of the pure colour of which they

reflect most. They absorb a great deal of the red beyond 6,000 A.U., and absorb almost all the violet, and yet these colours should be entirely reflected. Then the absorption is not nearly complete between 6,000 and 4,600 A.U.; in parts almost twenty (20) per cent. of the colour is reflected; the absorption is only approximately complete for those colours between 5,600 and 5,000 A.U.

With the blue pigments (fig. 3) the matter is even worse.

Wave Lengths A.U.—Yellow Pigment.

Fig. 1.

Wave Lengths A.U.—Red Pigment.

Fig. 2.

All these are much too dark; the printing ink is the best of them, and even this absorbs sixty (60) per cent. of the pure colour of which it reflects most; one of the carbon tissues absorbs no less than seventy-five (75) per cent. of its brightest colour. The ink does not absorb the red completely, as it should, but the other pigments are fairly satisfactory in this respect.

If we now consider the reproduction of five typical colours, of which we had secured ideal negative records, we shall see

how the defects of the pigments become apparent, first noting that the reproduction of any and every colour must be too dark owing to their general absorption.

A red (matching a mixture of spectral colours between 7,000

Wave Lengths A.U.—Blue Pigment.

Fig. 3.

and 6,000 A.U.) would be reproduced by full strength yellow and full strength red (i.e., magenta-pink) pigments. Now, it is seen that the yellow allows some of the blue to be reflected from the white paper, but this is not so important as the fact that the pink will allow so much of the yellow and yellow-green

to be reflected that the general colour will be orange rather than true red.

A yellow will be reproduced by the yellow alone; this will be fairly satisfactory, except for some degradation by reason of the absorption of the red and yellow, and the reflection of some blue, making it greyer than it should be.

Green will be reproduced by printing yellow in full strength and the blue in full strength. Some of the green is absorbed by the yellow ink, and a much larger amount of the blue ink, therefore the green is bound to look a very dark yellowish green rather than a pure green.

A blue (matching a mixture of colours between 5,000 and 4,600 A.U.) will be represented by the blue printing ink alone instead of this reflecting the whole of this light it absorbs almost three-quarters of it, and it will therefore be very much darker than it ought to be. A violet will be reproduced in full strength blue and full strength red; this is bound to be very much degraded, because neither of the pigments reflects all the violet as they should. In the case of the printing in the violet will be very reddish, because the blue is transparent to red instead of entirely absorbing it.

A true dense black could not be produced by the three printing inks, for example, because the red ink does not absorb sufficient of the blue green, and the blue ink does not absorb sufficient of the red; the black, therefore will have a slight violet tinge.

From the analysis of these pigments, which are far from the worst sold, but, on the contrary, are probably the best obtainable, it will be seen that even though filters and plates were perfect, exposure and development and all manipulations absolutely correct, an ideal which can never be quite attained there would still require to be considerable retouching of anything approaching a truthful rendering was to be secured on account of the poor pigments as yet at the disposal of the worker in three-colour.

A. J. NEWTON

## METHODS OF GETTING BUSINESS.

At the recent Convention of the Photographers' Association of Pennsylvania, Mr. J. C. Abel, editor of the "Photographer," read a paper on "Business-getting Methods," in which he spoke of ticket schemes, advertising cards and booklets, show-case and other means of attracting business to a studio. The discussion of his paper may be partly reported here, as it contains the experiences of several conventioners who may be supposed to represent the average middle-class photographer in the United States.

### A Successful Baby Contest.

J. E. Giffin (of Wheeling, West Virginia): I will give you some idea along the line I have been working. The first I will mention is that of the baby contest. I do not give free sittings in my studio, but I do have a baby contest. Last year I gave away fifty dollars in money to the prettiest child or the three prettiest children photographed at my studio. I offer no extra inducements, and make no reduction in prices other than the fifty dollars in money that I offer to those winning the prizes—first prize of twenty-five dollars, and so on. This year I have decided, as last year was a great success, to double the amount and make it one hundred dollars in prizes. That might seem to some photographers a lot of money, but when you take into consideration the great possibility of photographing children it doesn't amount to anything at all. This year I am getting out my three prize winners of last year, and am going to put them on a piece of paper about half the size of the ordinary newspaper page, so that if I want to publish it in a newspaper I can use about half a page. I put that out in circular form from house to house in my immediate territory, and mail it to

the surrounding towns. The pictures of the three prize winners last year will appear at the top of the page, full form, cabinet size with their names, the prizes they won, their addresses, etc. In five minutes you take up a bill of that kind you will appreciate it and hang on to it. It is a picture; it is not an ordinary handbill as is thrown around by advertising people, or even theatrical people who from time to time distribute literature after that style. The coming down on either side, there are little half-tones, also at bottom, of children. Then, of course, I go ahead with my real matter. There is no use in my trying to tell you in what form this out—I am just giving you the outline. I will say this: my experience last year has led me to repeat this; throughout the year I have had my attention called to it, and been asked: "When you going to have another baby contest?" But I will say to you above all things, when you do a thing of that kind, do it right, do it conscientiously, and do what you say you will do.

I want to take up one or two matters my friend Mr. Abel told you of; it has all been very interesting to me. One particular feature was sending out cards. As to the form of literature you send out, that, as you know by experience, is regulated by surroundings. I do not believe it would pay me to send out literature in Wheeling that Pirie MacDonald would send out in New York. I have a little caricature of myself which Mr. Abel criticised. I know it is not quite the proper thing, but I will tell you I do not believe I ever spent fifty dollars that gave me so large a return. These cards were mailed in a nice envelope, with a two-cent stamp, with a little reading matter underneath, and certainly has not done me any harm. I do not say you should do that, it might not do for you, but it has been a big thing for me.

### On Proper Booklets.

As to the matter of booklets, I do that every year. I try to get them up in form and with taste, and have as little reading matter as possible, and that has also resulted in great good. I send those select people and talk about them from time to time; as people enter my studio I ask them if they have received one of my little booklets, and if they have not we have a supply on hand and give them a copy.

Mr. Wills: Mr. Giffin referred to doing business and distributing different classes of literature in different communities. I certainly think he has made a point there. I do not think you can go into Wheeling, West Virginia, Charlottesville, Washington, D. C., and New York City, and distribute the same class of literature. I do not think you can go to a convention, pick out a certain class of work displayed in the hall, and go home and say you will turn that class of work; the people will not buy it. You have to determine on what your people want; you have to cater to the tastes of your community, and you must make the work that they will buy, and I do not approve the plan of picking out a few pieces, then going home and trying to copy them. I believe in proving your work and doing everything you can in that line. Let what you want to do is to make the work you can sell to your people and get the money for.

### A Matter of Individuality.

Mr. C. O. Towles (of Washington, D.C.): There have been a number of very interesting suggestions offered; some of them I partly agree with and some of them I do not. Referring back to the subject of business-getting in photography, I think that this is largely a matter of individuality. It is largely a matter that depends altogether upon the man as is the quality of work he sells to the community. I do not believe you have got to cater to all tastes to the public taste, because I think oftentimes the public taste needs cultivation rather than catering to. I think that is often the case, and in my roaming around over the country of which I cover pretty good scope, I find it in most instances the case that the public needs cultivation rather than catering to. Advertising, as I have said before, I think is an individual problem. I think, as Mr. MacDonald—who has been referred to—said the other day, that the show-case is the best medium for advertising that any photographer has got outside of direct touch and contact with his patrons. I think that a man should bend every effort to extend his name, and in putting his work before the public in such a manner that every dozen pictures he puts out would have a tendency to bring him a dozen new patrons, because certainly he has an opportunity that many other lines of business have not, that is, of getting into the hands of his patrons a product that is distributed among other classes of people, and is not entirely consumed by the people who buy of him. Every piece of his work, except one out of a dozen, perhaps, is distributed to some one else, each one of them bearing his trade mark, and each one is a speaking advertisement of the merit and quality of that man's work. Now, if his work is right there is no question about the balance of it; he is going to get the business; there isn't any question about it. You go into any community and show me the photographer who is doing the right kind of work and I will show you a man who pays his bills and is making money every time. If he is slipshod in getting his work out—careless in his products—the chances are that his trade is an indifferent one, and his prices are indifferent, and the amount of money he has in bank is indifferent, and all the advertising he can do isn't going to help him very much. As Mr. MacDonald said in New York, he would give a thousand dollars a year more rent for a room having a nice big show-case down at his door than for one without it. I believe he would be justified in doing it; that is, if the show-case is kept nicely. Note the people who stop and gaze at the photographs as they pass along the street. A good photograph has a charm, a magnetism, about it. Many a man and woman stops at a show-case to look at the pictures who don't think of having a picture taken; but sees the face of a friend nicely taken, beautifully mounted and prettily displayed, and that tends to create a desire for a picture, and the thought, "I will go up there and have some pictures taken next week." They go, and one brings another, and so the man's trade grows, if he is giving proper attention to the class of work, and to the display and general nature of his business.

### Convention-Attendance Pays.

Mr. Mitchell (of Maryland) said he began attending conventions about five years ago. In order to go he had to shut up his place of business, and he had a competitor. When he went to the national convention he locked up the Maryland building, and, picking up his home paper, saw his competitor's advertisement to the effect that "My gallery is open the year around." But when he went back he did more business in a month or two than he had ever before done in the same time. When he changes his advertisement he is careful not to conflict with that of his competitor. If he makes anything good he takes it down and shows it to the newspaper man, who gives him a little puff which is better than all the advertising. Last year he had three write-ups three weeks in succession on different matters, and they did him more good than the little advertisement he carries. Around the holidays he enlarges his advertising. That would not suit in large cities, but in a country town he feels that it has been a benefit.

### Show Case Ideas.

Mr. Abel: I will tell you one other method a photographer uses to get business. He posts the names each week of those who had photographs made the week previous, and everyone goes there every week to see the names in the show-case. That wouldn't get business in cities like Philadelphia, Washington, or Baltimore, but in small towns the names of the people are known to everyone, and the fact that Mrs. So-and-So had her picture taken last week is a piece of interesting news. People become interested, and next week they come around to have a picture taken.

Mr. Towles: A plan that I ran into some time ago might be of interest to some. In a town of twenty thousand people a man advertised for a few consecutive weeks that he would put a new picture in his show-case each day the following year, and he persisted in it conscientiously the following year. Every morning that year the first thing he did was to go to the show-case, take out a picture, and put a new one in. It was one of the greatest advertisements he ever had, and caused about a third of that entire population to make a visit to his show-case every day just to see whose picture was there. It struck me as being a good idea in a town of ten to twenty thousand, where a man knows everybody, and it will arouse more interest than anything else.

### THE METHOD OF PHOTOGRAPHING THE DEAD FOR PURPOSES OF IDENTIFICATION.

(From the "Lancet.")

At two inquests held last week on the bodies of persons unknown the coroner commented at some length on the very unsatisfactory character of the photographs of the corpses prepared by the police authorities, and suggested that means ought to be taken to make such photographs more like the individuals when alive, and therefore more useful for purposes of identification. The question raised by these criticisms, though it is obviously of some practical importance, does not seem to have received much attention from medico-legal writers in this country, and the bulk of the literature dealing with it is of foreign origin. One of the latest and most valuable contributions to its study is a paper by Dr. Minovici which appeared in the "Archives d'Anthropologie Criminelle" of November 15, 1904. The writer, who is director of the Medico-Legal Institute of Bucharest, gives in this paper a detailed account of the apparatus which he employs for posing the body and of the methods to which he has recourse for restoring the appearance of vitality to the features, his observations on this latter point being of special interest. One of the most serious difficulties in post-mortem photography is due, as is well known, to the loss of the brilliancy of the eyes, which has a large part in determining the characteristic expression of the individual. It has been usual to deal with this difficulty by the method suggested by Dr. Gosse\* of applying compresses to the eyes, but Dr. Minovici has found that much better results may be obtained by the use of artificial eyes, dark or light, according to the colour of the individual's iris. A natural appearance can be given to the orbital opening by introducing beneath the lids an extemporised speculum of lead foil or by fixing the upper lid to the ball of the eye by means of a fine pin. The jaws can be drawn together with thread, and by appropriate arrangements

of pins various emotional expressions can be given to the face. Even in cases where putrefactive changes have occurred, if there has been no actual loss of substance, the features can be in a large measure restored if the gases in the areolar tissues are evacuated through suitable incisions in the scalp and in the buccal mucous membrane. By the application of these methods in a case where the body had been immersed in water for six weeks Dr. Minovici succeeded in getting a photograph sufficiently life-like to establish the individual's identity. Photographs showing the successive stages in the preparation of the body in this case are reproduced in the paper, and give a striking illustration of the value of Dr. Minovici's ingenious artifices.

#### THE VALUE OF GOOD APPEARANCE.

The two photographs which we reproduce are from the trade circular of an American Company, the J. W. Butler Paper Co., of Chicago. They are sent out to illustrate forcibly the different effects of a letter written on poor stationery and good stationery, the man representing the letter and his clothes the stationery. The card bears the motto, "Clothes don't make the man, but they do make all but his hands and face during business hours." The illustrations are two views of one man, the difference being due to his clothes.

The lesson is one which may be impressed with particular appropriateness upon photographers. One direction in which good appearance counts is the photographer's stationery and advertising literature. The articles by Mr. W. J. Casey which appeared in these columns some time ago, offered many hints and suggestions which might be taken with profit to a studio. Good printing, the kind of printing which attracts business because it makes a favourable impression on the recipient, need not cost much more than printing which is poor enough to be useless for its purpose. We were recently shown a circular sent out by a photographer to possible customers, in which very little was said, but the whole effect of which, we found, had led our friend, who is no way connected with photography, to form the conclusion that the photographer did work of a high order. Merely a matter of good appearance. The particular circular we have since discovered was printed by Messrs. Pearce, of Brentford, and is being used by several professionals.

**SUNDAY Traders.**—Arguing before the Sunday Trading Committee that the opening of certain shops was necessary in Blackpool on Sundays for the sake of the excursionists, the Chief Constable of the town included the photographer among "necessities." "The bulk of the working people who get their photographs taken on the beach," he said, "never have a chance to be photographed in their best clothes except on Sundays."

In noticing the Royal Academy last week we omitted to mention that in the architectural room are hung two drawings, by Mr. C. H. B. Quennell, of Messrs. Speaight's palatial photographic galleries in New Bond Street.

\* La Photographie après Décès, Geneva, 1896.

#### A RESULT OF ORGANISATION.

In the reports of the Convention of the Professional Photographers' Society of New York, the question of the prices to be charged by schools elicited some discussion, and was quoted in particular at a point in regard to which agreement between the photographers of a town was very desirable if such work was to be done at a profit. We have since received a copy of the circular containing the terms agreed upon by the Rochester Section of the P.P.S. of N.Y., a body which represents, we are informed, all the photographers in the town. In sending it to us, Mr. Dudley Hoyt, the ex-President of the P.P.S., draws attention to it as an example of the practical manner in which members are getting together. There are a great many schools and colleges in the community, and in former years the photographers, actuated solely by a desire to swell the gross business of the year, have simply slaughtered prices until there was no more in school or class work for any one. When the season opened this year the Section met, and, as a result, the circular was agreed upon. The result has been that there is money in making school pictures now. The following is the text of the circular:—

To facilitate the fixing of uniform discounts upon school and college photographs, discounts have been agreed upon as follows:—

Number of persons contracted for.	Discount.
6 to 15 inc.	10 per cent.
16 to 25 inc.	15 per cent.
26 to 75 inc.	20 per cent.
75 or more	25 per cent.

The circular states the minimum list prices now existing in the respective studios upon which these discounts apply, and proceeds:—

It is agreed that these prices shall remain in force for one year from date.

That definite contracts be entered into between school or college committees and members of the Society based upon a specific number of students, for each of which a dollar must be deposited, before the prices go into effect; otherwise no discounts will be granted.

That school clubs and fraternities are to receive the same discounts and come under the same ruling as schools and classes.

That no further reductions of any kind whatsoever are to be made and that no concessions or inducements of any kind are to be made either directly or indirectly to members of committees or classes with the exception that on duplicate orders a discount of 25 per cent. from the respective list prices may be granted.

That any irregularities called to the attention of the members be reported immediately to the secretary.

#### ACTORS' PHOTOGRAPHS.

The following is the text of the proposals discussed by a deputation from the Actors' Association to the Professional Photographers' Association, a report of the proceedings in reference to which appeared in our last issue.

There being a certain amount of indefiniteness as the rights of theatrical artists who sit to photographers and of photographers to the negative made at such sittings, whereby the actor suffers considerable hardship as well as loss of income to which he is entitled, has been thought that a conference is desirable between the representatives of the photographic trade associations and the Actors' Association in order that the basis of a working agreement may be arrived at.

There are three classes of photograph to be considered:—

(a) The photographs taken for the purposes of advertisement, involving groups and scenes from plays about to be, or recently, produced.

(b) Photographs of individuals, taken at the express invitation of the photographer.

(c) The ordinary professional photograph taken of an actor on his own initiative, but paid for at a reduced or "professional" price.

In any one of these classes no hardship can arise where the sitting is preceded by a formal and just contract, signed by the parties embodying their mutual agreement, though there are contingencies which may arise out of such sittings which are seldom, if ever, provided for by the terms of such an agreement. It is suggested that a "General Form of Agreement" should be settled between the associations.

tations to be legally drafted and approved by counsel, which shall have the effect of obviating litigation.

But with regards to Class A:—

(a) It is in extremely rare cases that the individual members of a company can make any agreement with the photographer as to the terms on which they submit to having their portraits reproduced, there being no direct relation of actor and photographer, since the agreement is made between the manager and photographer; but it is clear that the right to put up a "photograph call" does not give the manager the right to enforce such a call, nor to dispose of the artist's right in his own face in any subsequent portrait, should he use it in response.

For the protection of the photographers, as well as to satisfy an undoubted equitable right, it is suggested that photographers, in making their agreement with the manager, should stipulate definitely and as a matter of course:—

"That all artistes posing for such 'advertisement' photographs shall be paid for their attendance a sum of (say) one guinea, and that it is agreed that the acceptance of that sum by the artistes gives to the manager (or photographer) the absolute and exclusive ownership of the negative so taken (except as hereinafter provided) with right of publication, reproduction, and alienation."

And further, for the avoidance of possible difficulties as to damage that might be inflicted on an artiste owing to misrepresentation arising from possible unhappy posing or fault in negative or other use of a like kind) that:—

"In all photographs of individual members of a company, or of portraits for which not more than two artistes are posed, the portraits so taken shall not be deemed available for printing or publication unless the approval of each sitter shall have been obtained of a 'proof.'"

(b) Where photographers invite the attendance of an artiste at the studio for the purpose of having his portrait taken, it will save misunderstanding, and obviate the risk of disputes if the photographer will clearly state, in such invitation, the purpose and intention of each offer.

This being a matter of individual contract, the terms will, of course, be private, and no suggestion can be made as to remuneration, but it is submitted:—

(1) That inasmuch as the portrait of an artist may be of great value to him for the purposes of his business, and may consequently of corresponding damage, no negative should be allowed to remain in existence to which the artiste opposes a reasonable objection, and should be broken on demand.

(2) That the "life" of a negative should be limited to a term of years, i.e., that the licensee to deal with or reproduce, should require renewal by the sitter after (say) two years.

(3) That it is desirable that in postcard reproductions of such photographs, the sitter should be offered payment for the rights on the same terms of a royalty on all copies sold.

(c) In this class of photograph it should be clearly defined that no right of publication or reproduction is vested in the photographer. His right is only to the property in the plate, and the right to reproduce at the instance of the sitter at the price determined between them. It is possible that the sitter may be willing to give to the photographer the right to sell the photographs as printed, and approved and accepted by the sitter, but this license should, if given, stipulate the retail price of such copies, and does not include the right of reproduction.

It is very strenuously urged that in all cases of professional photographs (a), (b), or (c), the "life" of the negative should be defined and established.

Questions arising out of a conference between the Professional Photographers' Association and a Deputation of the Actors' Association.

Query 1.—Is the P.P.A. agreeable to the making of such an agreement with theatrical managers, with regard to Class "A" of the A.A. proposals, as will make each member of the group or company photographed a party to the contract with the photographer?

Query 2.—Is the P.P.A. agreeable to the setting of a limit to the "life" of a negative, i.e., to define a period of years from the time of taking, after which it shall not be lawful to publish copies without express sanction of the sitter, so long as he be living?

Query 3.—Does the P.P.A. agree that no photograph should be published the negative of which has not received the approval of the sitter? And further, that negatives of which the sitter reasonably disapproves should be forthwith destroyed?

Query 4.—Does the P.P.A. assent to the contention that the payment by the sitter of a reduced fee (or "professional discount price") does not vest in the photographer the right of reproduction, nor the right to sell the negative or transfers of the same?

Query 5.—Will the P.P.A. agree to the proposition that "advertisement photographs" of plays should be withdrawn at the same time as the play they represent: unless a further agreement be made with the parties portrayed in such photographs?

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between May 7 and 12:—

WASHING PRINTS.—No. 10,831. A water circulator for washing photographic prints, plates, and films. Charles Edward Dodsley, 47, Shrewsbury Road, Birkenhead.

POSTCARDS.—No. 10,878. Improvements in photographic mailing cards. Samuel Aaron Markoff, 7, Southampton Buildings, London.

FILMS.—No. 11,033. Improvements in photographic films and their manufacture. John Edward Thornton, Altrincham, Cheshire.

PHOTOGRAPHY.—No. 11,072. Improvement in photography. John William Ippers, 65, Chancery Lane, London.

CINEMATOGRAPHY.—No. 11,168. Improvements in a combined photographic frame, and cinematographic apparatus. Henri Louis Huet, 53, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

CINEMATOGRAPHS.—No. 8,341, 1905. The invention relates to the simultaneous use of a projection lantern and cinematograph, the picture of scene of action being thrown on the screen by projection-apparatus, and the movements taking place in that scene are represented independently by means of one or several cinematographs. A source of light is used for the cinematograph, about 15 per cent. stronger than that of the projection-apparatus, whereby the cinematographic picture is rendered clear with respect to the background. A blind-slide is used behind the window of the cinematograph, which is provided with an irregular perforation or perforations by which the image thrown on the screen is irregularly bordered: the bordering line of the picture being rendered less visible on the background. The picture plate used in the projection apparatus is provided with a coating impervious to light and of the shape of the perforation in the blind-slide of the cinematograph, so that the portion of the background on which the cinematographic image is to be projected becomes of a more suitable tint. Paul Effing, 56, Charlottenstrasse, Berlin.

DEVELOPING SHEETS.—No. 9,248, 1905. The invention is the method of applying chemical solutions to photographic plates, films, papers, and the like in an evenly distributed quantity over the whole surface, and in such a manner that each portion of the surface is, during the whole time of contact, only subjected to the action of the portion of the developer immediately superimposed thereon. A paper is specially made of pure cellulose material, without chemical treatment, and coated with gelatine; also gelatine sheets alone or backed with porous or non-porous elastic supports, these materials being impregnated with developing substances. The method is described as applicable to fixing, reduc-

ing, etc. Douglas William Hart, 17, McDowall Road, Camberwell.

**MACHINE PRINTING.**—No. 17,605, 1905. An apparatus for printing from photographic negatives, comprising an arrangement for moving the negative and web together, a stationary exposing device presenting a narrow slot, a supply roller and a winding-up roller for the sensitised web, means for reciprocating the negatives and the web between the pressing and exposing devices, and means for feeding the web forward after each to and each from passage. Frederick Heinrich Lange, 52, Steinmetzstrasse, Berlin, and Oscar Prange, 75, Gitschinerstrasse, Berlin.

**COPYING MACHINE.**—No. 26,612, 1905. The claim is for an illuminating device for a photographic copying machine, in which the illuminating chamber is provided with a movable bottom adapted to be passed over the lamps. The photographic plate B is placed on the illuminating chamber reservoir A. The copying or printing band C which is to be passed over it, is alternately pressed against the plate B by means of the cover D, and released. During such pressure the illumination must take place, whilst during the lifting of the cover D the illumination must be interrupted and the forward movement of the band C effected. The intermittent illumination is effected by means of the movable bottom E having apertures for passage of the electric lamps F. This bottom E may act at the same time as a reflector, since a diffused light is the most suitable for the production of photographic prints or copies. The bottom E is impenetrable to light so as to render

the upper part of the chamber A entirely unilluminated when the bottom is raised during the period it is desired to cut the light off (as shown in dotted lines). In the uppermost position of the bottom the apertures therein for passage of the lamps bear against the sockets of the lamps and are thus closed. If the bottom E is impenetrable to light, the latter cannot enter the upper part of the chamber in this position, but, on the other hand, in the lowest position of the bottom E, the lamps illuminate the chamber to their full extent. This operation can be assisted by providing the surface of the bottom with a reflector so that no direct but only reflected light is used. It is obvious that the apparatus may be used in a vertical or inclined position instead of in a horizontal one as shown. Otto Lienekampff, 9, Johannisallee, Leipzig-Reudnitz, Germany.

**CAMERA MOVEMENT.**—No. 1,317, 1906. The invention consists of a folding camera in which on the opening of the cover forming the slide way, the forward movement of the lens carrier into the position required for "infinity," is automatically effected by means of a spring roller which is connected with the lens carrier by means of traction devices. Optische Anstalt, C. P. Goerz Aktiengesellschaft, of 44, 45 and 46, Rheinstrasse, Friedenau, near Berlin.

**PNEUMATIC COPYING FRAMES.**—No. 7,253, 1906. The invention applies to large printing frames in which the drawing to be copied and the sensitive paper are pressed against the glass of the printing frame by means of an airtight cover mounted on a rim which is pressed tightly against the glass whilst the air is exhausted. To secure contact of the rim with the plate a pressure bar is necessary, but the present claim is for means for pressing the cover against the transparent or translucent plate by atmospheric pressure, consisting in the formation of a hollow space between the cover and the plate along the rim of the surfaces to be pressed together, such space being made to communicate with

the air-exhausting apparatus so as to exhaust the air therefrom simultaneously with and to the same degree as the exhaust from beneath the cover. Siemens-Schuckert-Werke, Gesellschaft mit Beschränkter Haftung, No. 3, Askanischer Platz, Berlin.

## New Books.

**Die Grundlagen der Farben Photographie.** By Dr. B. Donath. Brunswick: Friedrich Vieweg und Sohn. 5s.

The purpose of this work as outlined by the author in his preface is to present a clear conception of the theory involved in colour photography; it is no handbook nor complete instruction in photographic processes. Read in this light it is certainly satisfactory up to a certain point.

It is divided into two sections, the first dealing with the direct processes of colour photography, such as those of Becquerel, Poitevin and Lippmann—the last naturally absorbing the greater portion. In the practical instructions for this process we note the omission among sensitisers of methyl violet, which has been adopted by Lippmann as the most satisfactory, and also all mention of the communication which appeared in our issue for June 30, 1905, p. 500 which suggests the possibility of multiplying prints in colours in the ordinary way in the printing frame.

The bleach-out process is also dealt with fully, and here the author has had the advantage of private communications from Dr. Neuhäuss, who, it is well known, has made a special study of this subject. We refer to this communication under "Ex Cathedra."

The second edition of the work is devoted to indirect processes and the historical notes are sketched in with a fairly liberal and accurate pen, though we note that in one place the date of H. W. Vogel's discovery of the orthochromatising action of dyes is given as 1865, whilst further on it is given correctly as 1873.

There is one notable omission, and that is any reference to S. Wm. Abney's work on the colour sensations; otherwise the chapter dealing with this subject is extremely satisfactory.

In dealing with the sensitising dyes, one notes, however, a mere casual notice to pinachrome, and no mention of pinacyanol or dicyanine, ethyl-red alone being considered at any length. One may question, too, whether the author's statement that most colour filters present gaps in the yellow-green and blue is correct. No specific formulæ are given for filters, merely those regions which should be transmitted, and these only for an additive or projection system, and according to Dr. Miéthe.

Sensitising of the plates is again merely treated from the point of view of the use of ethyl-red alone, nor is any mention made of von Hübl's suggestion as to the use of alcohol and omission of ammonia in the sensitising bath, which considerably improves the keeping powers and does away with the necessity of washing and rapid drying.

Possibly our objections may be considered somewhat captious particularly when the work as a whole is extremely readable, and gives one a very clear enunciation of the theories involved. A three-colour print from negatives taken by Dr. Miéthe is given, the constituent prints being also shown, and a useful bibliography of the authors and papers quoted is included at the end.

**"To Make Bad Negatives into Good."** By A. Horsley Hinton. London: Haeßell, Watson, Viney, Ltd. 4d. net.

The man who can chat—not write or discourse—on intensification and reduction, could probably interest a Patagonian in local optics or the law of primogeniture. Certainly, Mr. Horsley Hinton does not convey information on the ways and means of improving negative without ever being technically dull. Placing ourselves in the position of the youthful reader we can feel our palate tickled to try what intensification is like, and whereunto in the whole world of remedial we are to liken ammonium persulphate as the destroyer of photographic ills. The little book, which is well-printed and contains some half-tone examples on art paper of a negative's defects, deals also with the making of a new negative and with the elements of spotting and retouching. Throughout the technical pill is carefully enveloped in colloquial jam, and at times the jam is laid

a little thickly. But what of that? The young photographer is glad to take an interest in the technics of his craft, and on this point alone Mr. Hinton deserves to be thanked for discharging the duties of a guide so agreeably.

**The Red and Blue Books.**—The two publications of the Royal Photographic Society Affiliation and of the Scottish Federation respectively, which have appeared within a few days of each other, are pieces of evidence of the multifarious activities of photographic societies. The Red Book grows a little thicker year by year; the Blue Book, on the other hand, evidently dreads obesity as a disease, and strives successfully to retain the waistcoat pocket size at it assumed on its first issue. Thus, it does not set forth the particulars of each federated society as does the Red Book those of the societies in the Affiliation. Its chief aim appears to be the assistance of the Scottish photographer when on tour in his own or other lands, in pursuance of which it prints a long list of resorts and beauty spots, with the addresses of Federation representatives and of the available dark-rooms. A list of photographic experts who are willing to advise Federated photographers is another of its commendable features. The Red Book also actively watches the interests of its touring readers by a comprehensive list of particulars relating to permission to photograph. In many cases the production of the Red Book is sufficient permission. The innovation of last year of embodying tickets for the R.P.S. Exhibition in the Red Book is continued, a proof, we may suppose, that the plan was found convenient and labour saving.

## New Apparatus, &c.

the "Graflex" and "Premo" Reflecting Cameras. Sold by Kodak, Ltd., Clerkenwell Road, London, E.C.

The first-mentioned of these two cameras has constantly been referred to by writers in the American Press as a standard instrument of the reflex pattern in the States, and so far as we can learn has earned golden opinions for itself among photographers who undertake work for the Press, or devote themselves to other branches of accurate photography. And the "Graflex" possesses certain

Fig. 1.

Fig. 2.

features which mark it out among reflex cameras of any country, chief among which is a special accessory mirror in the hood by which the image on the ground glass can be examined when the camera is held at the eye level. The two figures 1 and 2 show the two methods of holding, and emphasise the obvious advantage of the instrument in permitting the taking of a higher point of view, often a matter of very great importance when photographing at public events.

The shutter of the "Graflex" is of the focal-plane type, and of the multiple slit variety, containing five slits of different widths in the complete blind. This arrangement we have known to be very

convenient in practice, and in the "Graflex" the alteration from slit to slit is very conveniently made. In other respects the instrument is one of the highest class, which is not to say that it is overloaded with movements or finished with unnecessary cabinet-making. In our estimation it is produced with a very careful eye to its practical performance, and for that, among other reasons, may anticipate receiving the notice of all who contemplate adopting the reflector principle in hand-camera work. It is made in two sizes, quarter-

Fig. 3.—The Graflex fully opened.

plate and 5 by 4, the former costing, without lens, £15 12s. 6d., and the latter £17 14s. These prices, it may be judged, do not apply to an instrument which has not received, both in its initial stages and in its regular construction for the market, all the care and attention to details which a camera of this class demands from its maker. That such is the case with the "Graflex" is evident from the ease and smoothness of the working parts, and the

Fig. 4.—The "Premo" Reflex Camera.

freedom of the mirror and shutter from jar and abnormal noise when in operation. A critical inspection of the camera justifies the opinion that it is a highly efficient instrument of its class.

The "Premo" reflecting camera which the Kodak Company are also introducing differs from the "Graflex" in having a reversing back. It has a focussing hood which is of convenient depth, and erects itself on drawing the release. The shutter movements as re-

guards setting the shutter and altering the width of slit are all conveniently made, and the range of exposures are comprised between 1-1,200th and 1-75th of a second, time exposures, both in the case of the "Premo" and "Graflex," being made by opening the shutter to the full width of the plate.

The camera is handsomely made, and in the 5 by 4 size costs £17 15s.

Thorpe's Direct Vision Diffraction Reading Pocket Spectroscope. Made by R. and J. Beck, Ltd., 68, Cornhill, E.C.

This new diffraction pocket spectroscope is a very handy form. The slit, which is made of platinoid, and adjustable with a milled head, has one of its jaws movable, and can be readily focussed by sliding the tube out. A first order spectrum is used and is of considerable brilliance; the dispersion is very nearly normal, and is about 30deg. There are two distinctly good features, which will make this little instrument very valuable for determining the position of any unknown line. The first is a brilliant little triangle of white light, with the apex just above the spectrum, which can, by means of a micrometer screw, be made to travel very rapidly from end to end of the spectrum so as to coincide with any line. The second feature is that the micrometer screw is provided with a milled head, divided into 500 divisions, which enable one with very slight shift of the eyes to read at once the division on the scale correspond-

ing to the position of the line, a small eye-piece enabling these divisions to be very easily read; we were thus able to locate the positions of the eight principal Fraunhofer lines, and their scale reading, in less than five minutes, and from these, of course, with the aid of a table of wave-lengths, the position of any other unknown line could be read off. The construction is very clearly shown from the accompanying figure, in which the upper tube is the indicator, provided, as will be seen, with a focussing adjustment, the image of which is thrown down to the spectrum by the small right-angle prism, whilst underneath is the micrometer screw drum and eye-piece. Although not meant to show it, there is no great difficulty in seeing the second order spectrum also.

The instrument is very compact, and should be very serviceable, as the dispersion is quite sufficient to distinctly separate the D lines. The price of the complete spectroscope is £4 4s.

The Photo Appliance Company, Englefield Green, Surrey, send us an accessory which they have just brought out in the shape of a single lens of  $1\frac{1}{4}$  in. diameter and about 6 in. focal length. It is mounted so that it can be attached to the camera for use as a supplementary lens, and in this capacity may be applied for various purposes of copying, as it forms, with the lens with which it is used, a combination of considerably shorter focus.

Messrs. Kodak, Limited, call our attention to recent improvements in the well-known "Premo" film-pack, whereby it is possible to remove one or more films for development before the whole pack is exposed. As now issued, each of the twelve films in the pack may be removed and developed before proceeding with the exposure of the next.

RECEIVED.—Self-toning P.O.P. (Wellington and Ward, Elstree, Herts); Boryl-Caramel (Lichtenstein and Co., Victoria and Royal Albert Docks Chemical Works, Silvertown, London, E.). We shall report on these new introductions in a forthcoming issue.

## New Materials.

Autotype Texture Films. Made by the Autotype Co., 74, New Oxford Street, London, W.C.

An old device in modern commercial form for convenient use brought to our notice by the Autotype Company in their new "texture films." The method of imparting the appearance of texture to a print by the expedient of interposing between the negative and the papers a transparency representing some particular fabric or surface is here placed at the disposal of the photographer in an extremely handy shape. Each "texture film" consists of such a transparency, prepared on thin celluloid by the carbon process. At present nine different varieties of texture are available, most of these representing canvas or other fabric, but one or two possessing a less definite structure and giving the print the appearance of being made on rough drawing paper or wood of a not very pronounced grain. The method of use is, as we have said, simply to place the film between the negative and the paper during the whole time of printing. The celluloid is thin enough to prevent any loss of definition, except in the case of such work in which highly critical

definition is required, work, in fact, of a kind for which the qualities imparted by the "texture films" would never be desired. The finished results on smooth matt papers are most realistic at a short distance, the print possessing the appearance of a rough surface. The advantage of the process over carbon with transference to such rough materials is very great, as the long soaking before transferring is entirely dispensed with. The method, however, is just as applicable to silver and bromide printing, and there would seem to be a distinct advantage in using it for prints in which the effect of texture is to be reproduced in half-tone or other reproduction process, inasmuch as the pseudo-texture is free from the corrugations and irregularities of surface which make such originals the bane of the process man. The prices of the films are 3s. 6d per sheet,  $14\frac{1}{2}$  x 10 inches, and 1s. per sheet suitable for cabinet pictures. The illustration gives a fair idea of the effect produced by one of the films.

"Rotograph" Slow Bromide Paper. Made by the Rotary Photographic Company, Ltd., 12, New Union Street, Moorfields, London, E.C.

In issuing a new brand of paper, the Rotary Company are acceding to the wishes of their clients who prefer a slower emulsion but one considerably more rapid than the Rotary gaslight paper "Rotox." "Rotograph Slow" requires about nine times the exposure of the ordinary rapid paper, and such a slower paper will doubtless be appreciated for the somewhat different character of its results. The paper, as we have found it from the sample supplied to us, bears the same relation to the more rapid brand as the observable in other cases—that is to say, the prints are more brilliant, and for that reason the paper should assist users of "Rotograph" papers in handling flat or fogged negatives. The paper deserves all the good things which have been said of its more rapid prototype, and perhaps that is as high praise as can be accorded to it. It is issued in five grades: A, thin glossy; B, thick glossy; C, thin matt smooth; E, thin rough; H, half-matt; and is sold in the usual sizes and at the usual prices.

## CATALOGUES AND TRADE NOTICES.

MESSRS. KODAK, LTD., draw our attention to a circular of reductions in the price of Premo cameras.

THE Charles Urban Trading Company, 48, Rupert Street, announce long cinematograph films of the San Francisco disaster taken on the spot by their American agents.

The Kodak Company are to be congratulated on the cover of their newly issued list of amateurs' photographic requisites. At the moment when the West-End policeman is the observed of all observers it is something more than a coincidence to represent him at the instant of being photographed in a stylish thoroughfare by a gorgeously apparelled lady. The contents of the list appear equally up to date.

A VERY stylishly produced list of prices for architectural and engineering work is sent us by Mr. Charles H. Horton, Rupert Chambers, Quay Street, Bristol.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held May 22, Mr. F. F. Renwick in the chair. A paper by Messrs. C. E. K. Mees and S. E. Sheppard was read in summary by Mr. Sheppard. The paper dealt with "The Theory of Fixation and the Action of Thiosulphate in Development." In their experiments the authors had measured the densities of small portions of plates in course of fixation in very weak thiosulphate solution. The piece of plate was placed in the Schultz cell of the spectro-photometer, the volume of solution thus used being 2 c.c.s., equivalent to .006 of a gramme of thiosulphate. To avoid errors from scattered light the observations were made by diffused light from a screen of opal glass, and a filter of yellow gelatoid was also employed to prevent darkening of the plate during or after fixation. Experiments made in this way showed that the addition of potass bromide up to N/10 strength did affect the rate of fixation, which was found to be directly proportional to the concentration of the thiosulphate. Ordinary plates were found to fix more quickly than rapid ones, probably owing to their greater fineness of grain and lesser content of iodide. In regard to the theory of the process the authors concluded that the efficiency of the fixing agent depends upon the stability of the compound, or complex ion, formed with the silver halides. The course of fixation appeared to be governed by the rapidity of the penetration of the fixing solution into the gelatine film: the chemical action was probably very fast compared with this latter process. The velocity of fixation was found to increase up to a certain point and then remain constant.

In examining the fixation of films tanned with formaline the authors found no difference in the velocity of fixation between the tanned and untanned films, nor was it possible to distinguish any difference between exposed and unexposed plates in this respect. Stirring was found to accelerate fixation, and also to modify the course of the reaction.

The authors' general conclusions were that in fixing three processes are concerned. First, the diffusion into the film as a whole of the fixing solution. Secondly, diffusion through the grain of the plate; and, lastly, the chemical action of the fixer.

In studying the action of solvents of silver halides in developers they examined development with ferrous oxalate and with alkaline developers, containing in both cases small quantities of thiosulphate. They ascribed the well-known alleged accelerating action of hypo in the iron developer to the formation of a germ image of silver sulphide from the action of the acid developer on the thiosulphate. In the case of alkaline developers the effect of the hypo is to retard development, similarly to bromide, but much more irregularly. A brief discussion, in which the Chairman, Mr. C. P. Butler, and Mr. C. E. K. Mees took part, followed the reading of the paper.

The lateness of the hour—Mr. Sheppard's summary had occupied sixty-five minutes—prevented the reading of the second paper—"Some Notes on the Sizing of Papers for Printing-out Emulsions," by Mr. P. L. Thornton—but Mr. Thornton summarised his communication in the two words "animal sizing." He then proceeded to demonstrate the properties of the paper "Mattos," in which his ideas of sizing have been carried out. A similar demonstration has been lately reported in our pages, hence we need not repeat the description of the manipulation, except to say that the speaker exhibited a number of prints and a variety of fabrics, in addition to specimens of the new "Mattos" papers now ready for the market. A number of these were of smoother surface than the original papers. A large number of prints were handed round and greatly admired. Mr. Thornton also showed the very simple methods necessary for toning the prints with gold and platinum.

WORTHING CAMERA CLUB.—A most attractive summer programme has just been issued to the members of the W.C.C., including a list of ten excursions and eight monthly competitions. The first excursion took place last Saturday, and the members availed themselves of this opportunity to present Miss Rosa Crouch with an Heyde Actinometer, as a recognition of the help she has given her brother in his work as hon. secretary to the club.

LEEDS PHOTOGRAPHIC SOCIETY.—Dr. Tempest Anderson, B.A., F.G.S., received a very enthusiastic reception by the Leeds Photographic Society, upon his return from Vesuvius, last week. The committee of the Society entertained him to dinner at Powlney's rooms prior to his lecture. After dinner Dr. Anderson delivered his lecture, "South Africa with the British Association," to a crowded audience in the Philosophical Hall.

CROYDON CAMERA CLUB.—The session closed on the 16th inst. with a lecture by Mr. C. E. Kenneth Mees, on some general principles underlying orthochromatic work, with particular reference to the production and properties of orthochromatic plates, of a high degree of sensitiveness to the entire visible spectrum. As the text of the paper will shortly appear in these pages, it will be sufficient to briefly indicate here the salient features so far as they relate to the discussion which followed. The President, Mr. W. H. Smith, in a few introductory remarks, humorously reminded his hearers that when Mr. Mees first joined the club he somewhat failed to appreciate that the ordinary member did not exactly revel in the calculus or other forms of mathematical recreation. Happily, since then, he had stooped to more graphic means of expression and simpler forms of explanation, for which they were all duly grateful. Mr. Mees, whilst admitting the truth of the charge brought against him, hoped that the present and the future would wipe out "the unhappy past" alluded to, and thereupon proceeded with his lecture. The spectra of various plates were first shown, including many by Mr. A. J. Newton. Much interest centred in yet another new plate, being introduced by Messrs. Wratten and Wainwright, which may be broadly stated to combine the valuable properties of a pinachrome, and a pinacyanol bathed plate, without the gap in the green which the latter presents. With this plate, sufficiently good correction can be obtained for nearly all purposes with a  $\times 4$  filter. With a  $\times 8$  filter the intensity and luminosity curves practically coincide. The last filter, Mr. Mees said, was unfortunately apt to fade if exposed to strong daylight. The lecture concluded with a capital diagrammatic method, showing how light-filters acted, and a series of slides representing spring landscapes, by Mr. H. P. C. Harpur. The slides were from negatives taken on bathed pinachrome plates, behind a  $\times 3$  light-filter, and nothing could have more conclusively shown the value of a highly orthochromised plate and adjusted filter for faithfully rendering

landscape subjects at this time of year. Mr. Baldock queried whether any particular screen could be said to have a given multiplying factor. He also thought a differentiation should be drawn between a coloured pigment chart, shown by Mr. Mees, and colours in nature. The eye was a very poor judge of colour; for instance, when using a solution of bichromate of potash as a filter, the eye entirely failed to detect a considerable amount of green let through. Mr. Woodland (a visitor) enquired whether the multiplying factor varied with the time of day. He would also like to know how long bathed plates would keep in good condition. The lecturer, in reply to the above speakers, said that the multiplying factor of any filter was fairly constant to daylight so far as black and white was concerned; neither did it materially vary at different hours of the day, except, perhaps, at sunrise and sundown. Any variation, at all events, would be less than unavoidable errors in manipulation. Coloured pigments and colours in nature acted in precisely the same way, viz., by absorption. Bathed pinachrome and pinacyanol plates had kept perfectly for ten weeks; he could not say more until further time had elapsed. He objected to the use of bichromate of potash in fluid filters, as it cut the blue too abruptly. Mr. E. A. Salt drew Mr. Mees' attention to a report of some observations of Baron von Hübl, it being alleged that academic theorists often lead others astray, as they failed to distinguish between pure spectral colours and radiations from coloured objects, as might produce an identical effect on the visual organs. Von Hübl had instanced chrome yellow as reflecting not only yellow, but red, orange, and green, and had pointed out that chrome yellow and a spectral yellow corresponding in visual effect would have a widely different action on the plate. He (the speaker) had his own opinion as to academic theorists' views in the matter, but would be glad to have the lecturer's. Mr. Mees, replying, said no one theorist, or otherwise, would ever suggest the hypothetical misconception advanced. If chrome yellow reflected back the colours mentioned, then, obviously, all that would be required to correctly translate it in monochrome would be a pan-chromatic plate and adjusted light-filter. Mr. Salt, continuing, enquired whether in three-colour work the secondary spectrum existing in most lenses impaired definition; he should expect to find this to be the case. He next drew attention to a point Mr. Mees had raised a long time ago, as to the lessened latitude a plate possessed when exposed behind a light filter. Had he any figures on the subject? Personally, he had found when working with a filter, one had to be careful to obtain approximately correct exposure. He had also experienced a far greater tendency to halation when employing a filter. Without a filter, the blue rays chiefly acted upon the plate, and being in great measure absorbed by the film, were prevented from being directly reflected back by the glass support. With a filter the blue rays were more or less cut out, and the less actinic rays brought into action; these traversed the film more readily, with possible attendant halation. When using highly colour-sensitive plates with a filter in landscape work, the use of a black backing appeared very desirable. Mr. Mees agreed with Mr. Salt's remarks on halation; the remedy was to back the plates as suggested. An ortho. plate behind a filter had less latitude than when exposed without one, but he would have to reserve a full consideration of this until a later date. The residual chromatic error in an anastigmatic lens did not in three-colour work perceptibly degrade definition, the secondary spectrum being very close to the focal plane; only under very severe and critical conditions would an apochromat show a difference in its favour. Mr. A. J. Newton concurred: a good quality rapid rectilinear met the requirements of three-colour work; in only one case, that being a lens of extremely long focus, had he found chromatic error obtrude itself in practice. He warmly congratulated Mr. Mees and Messrs. Wratten and Wainwright on their latest plate, and in this connection he thought the first-named had exaggerated the fading properties of the  $\times 8$  filter. He had exposed one to bright sunlight for a whole day, and the amount of fading was insignificant under ordinary conditions, and used with care the filter should remain in good condition for a very long time. The President, in proposing a vote of thanks to Mr. Mees for a very interesting and certainly the most important paper they had heard during the session, also acknowledged the indebtedness of the club to Mr. S. H. Wratten, and to Mr. A. J. Newton and Mr. W. J. Smith, of the Bolt Court School. The last-named, he understood, had kindly assisted Mr. Mees in the preparation of his lecture. He was very pleased to see so many visitors present that night.

## Dews and Notes.

**NATURAL Backgrounds in Studio Portraits.**—A correspondent calls our attention to the publication, some thirty years ago, of a process of obtaining natural backgrounds in portraits without resort to combination printing, which is practically identical with that of Dischner, described in our issue of May 4. The process was devised by a Mr. Tilley, of Stafford, was demonstrated by him before photographic societies of that day, and attracted a good deal of attention at the time. A full description of it will be found in "The Photographic News" of September 24, 1875, but we cannot discover that the process ever became generally used. Probably it did not, owing to the fatal necessity of keeping the background transparency out of contact with the wet collodion plate, which was at that time universally used.

"THE Magazine of Fine Arts," the handsome monthly of Messrs. George Newnes, reproduces in its May issue two photographs by R. Dührkoop from the present exhibition at the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY. Among other contents in an interesting number are "The Chalk Drawings of William Strang," "Sketches of John Constable," and "A House for an Art Lover."

A FEATURE of the "Country in Town" Exhibition which will be held from July 5 to 19, in the Whitechapel Art Gallery, will be photographs illustrating what can be done to beautify urban gardens, streets, and parks, and our readers are invited to help by taking photographs and exhibiting prints. There are some very beautiful views in some of the London parks, for instance, and no difficulty would be found in obtaining the necessary permission to photograph them. All inquiries should be sent to the Honorary Secretary, Mr. Wilfred Mark Webb, at Toynbee Hall, Whitechapel, E.

MESSRS. GEE AND WATSON send us a reference circular of mechanical tints and stipples which they can offer their customers for use with blocks from black-and-white drawings. The circular illustrates the thirty-six varieties available.

CINEMATOGRAHY Day by Day.—"The Daily Bioscope" is the title of the exhibition of animated photographs to be held at 27-29 Bishopsgate Street Without from noon till 9 p.m. The exhibition is to present events of the day on the screen with all possible speed. The cinematograph arrangements are in the excellent hands of Messrs. Gaumont, and at a Press view which took place on Wednesday last we learned that the intention of the management is to supplement the daily newspaper by cinematographic methods, and to provide cheap and attractive entertainments in all parts of London. At the noon hour on Wednesday the exhibition was thronged with City men.

MRS. ALSTON, of Alston's new process of crystoleum painting, has acquired larger premises for her studios, at 52, New Bond Street, where free demonstrations are given on Tuesdays and Fridays, 11 to 12 a.m.

A FLASHLIGHT Accident.—Whilst assisting Mr. Jaques, a photographer, in taking a flashlight photograph at the Leysian Mission, Islington, last week, one of the assistants, in working the flash, did not get sufficiently clear at the moment of the flash, and was rather badly burned.

MESSRS. CHANCELLOR AND SON, photographers, of Dublin, have been granted a special Royal warrant, appointing them photographers to his Majesty. The warrant comes through his Majesty's Privy Purse Department, and indicates the King's personal appreciation of Messrs. Chancellor's work and services to his Majesty.

An exhibition of colour photography, including a number of specimens, which were recently shown at the BRITISH JOURNAL OF PHOTOGRAPHY, was opened last week at the studios of Mr. Frank R. Moffat, Princes Street, Edinburgh. Sir William Turner, Principal of Edinburgh University, who declared the exhibition open, complimented Mr. Moffat on enabling the public to inspect it. Mr. J. Tudor Cundall, B.Sc., President of the Edinburgh Photographic Society, said he had seen a great many exhibitions of the kind, but he had always come away with a keen sense of disappointment. In many cases the reproductions were excellent, in so far as general objects were concerned, but in the quieter colours of natural objects the process sadly failed. There was evidence in the exhibition of

very great step in the right direction. Flesh tones and landscapes are very satisfactorily reproduced. He looked forward to the time when colour photographs of natural objects might be made in a convenient way.

SELECTION of work by the members of the Linked Ring will be shown at the forthcoming Salon of the Photo Club of Paris.

AN exhibition of photographs, arranged by the Photo-Secession, has been held for the past four weeks in the Pennsylvania Academy of the Arts. To quote from a brief prefatory note: "The pictures, with very few exceptions, been chosen from those which were in a series of exhibitions at the Photo-Secession Galleries in New York during the present season. They summarise in a broad way the trend of that international movement of which the Photo-Secession is the organised American exponent, a protest against the conventional conception of what constitutes pictorial photography." The poster of the exhibition is from the striking original photographically designed by Mr. Edward Steichen for the firm of C. P. RTZ.

## Correspondence.

### THE THEORY AND PRACTICE OF INTENSIFICATION.

To the Editors.

Gentlemen,—Mr. Thorne Baker, in his letter of May 7, accuses me having taken some of his phrases too literally. May I ask what is the precise value of a scientific article that is not to be read literally? His second article he stated, in reference to chromium intensification, that "the bleached" image after washing may be redeveloped in an alkaline-reducing solution, when certain chromium compounds precipitated upon the original silver, etc. If this sentence is not "too literally," but in an ordinary common sense fashion, no interpretation is possible, and that is, that the developer precipitates certain chromium compounds. A second and third thing of Mr. Baker's articles do not reveal the slightest suggestion that the chromium deposit is precipitated by the silver and not by the developer. On the contrary, these re-readings simply tend to affirm my previous idea that Mr. Baker was indulging in pure speculations with regard to a process that he had not investigated and did not understand. He states that he read our articles before writing the subject, and that he does not think his statements "disagree" in the facts we already know about chromium intensification. Mr. Baker is under this impression I am afraid our articles must have been very obscurely worded, and that our explanations must have been very inadequate, for repeated readings of his articles fail to reveal any points of agreement.

I see that Mr. Baker has not yet answered Mr. S. E. Sheppard's query as to the meaning of the so-called densities given in various places. As Mr. Baker has definitely referred to these numbers as densities we may presume that he considers them to be properly described, unless we are again guilty of too literally interpreting his statements. If, however, these really are densities, many of our readers would be only too glad to learn how to measure a density of 27.1, and where to obtain the necessary photometer. If they are, on the other hand, only densities multiplied by ten, as Mr. Sheppard suggested, it would be interesting to know the reasons for so multiplying them, and for still calling the results "densities." As to the process of intensification by rehalogenising the image after exposing it to the light, I can say positively that no such effect takes place when bromine, chlorine, or iodine are the halogens employed, therefore I shall be much interested in Mr. Baker's promised further information. But I may be permitted to hope you will confirm it by practical experiment before proceeding to the next stage of publication.

My experience with the permanganate process is on all fours with that of the continental writer quoted by Mr. Wall, but I see that the same writer suggests the formation of chromate of chromium (chromium dioxide) in the chromium process, and with this I cannot quite agree. The point cannot be settled definitely, as direct analysis is impossible, but we conducted a number of comparative tests that strongly suggested the presence of, not the dioxide, but the tetroxide. These tests lasted over some weeks, and were repeated again and again, and the result showed that while the unknown compound behaved in almost precisely similar fashion to the tetroxide, it was affected by the various reagents to a rather different degree, and at a very different rate to the dioxide, which appeared to be a more stable compound. Here I may take the opportunity of correcting a slip in my former letter, where I referred to the developer reducing the chromium compound to a lower oxide. If the compound is dioxide the statement might be correct to a certain extent, but if it is the tetroxide it is obviously wrong, as that is already a lower oxide than chromic oxide. The precise nature of the change that takes place cannot be suggested. All that can be said is that all these brown compounds are decomposed more or less readily by water and by alkalis, which reagents remove chromic acid, and leave some compound that eventually can be identified as chromic oxide. Similar final results are attained with either the dioxide or the tetroxide, but it is obvious that the mechanism of the change must be different in the two cases.

With regard to Eder's solution, referred to by Mr. Wall, we did not find "no intensification," but only very slight intensification. Small traces of chromium compound exist in the image, but the great bulk of the compound is in the solution, which contains too much acid and is too powerful a solvent.

In respect to uranium intensification, Mr. Baker's recent letter does not seem to be in accord with his articles, where he distinctly recommends different formulæ to meet different cases. I am, however, disposed to agree with him that there is something wrong in the idea that the colour depends on varying the formulæ. The brown colour that is supposed to be due to an excess of uranium I am more disposed to attribute to a deficiency of ferri-cyanide, and consequent incomplete action, for the same effect can be produced with almost any uranium bath if the action is retarded. In bromide toning I have never been able to control the colour satisfactorily by varying the proportions of the ingredients, though it is easily done by varying the dilution. Complete toning always gives practically the same colour in my hands, and properly brown tones are only attained as the result of very partial toning. Good sepias can be produced only by partial toning, but there are several ways of arriving at them. Complete toning gives a red-brown of very constant tone, and a final reducing bath of sulpho cyanide and ferri-cyanide to remove the silver is the only satisfactory method I know of attaining a good red. I once, however, used a ready-made one-solution uranium intensifier, that converted the image into a pure red transparent stain. The composition was a secret, but it was evident that the solution removed the silver, and I think that potassium cyanide was probably an ingredient. It was a useful intensifier, but I never solved its mysteries.—Yours, etc.,

C. WELBORNE PIPER.

### LUMINOUS BACTERIA

To the Editors.

Gentlemen,—In the last number of the BRITISH JOURNAL OF PHOTOGRAPHY you refer to the work of Molisch, of Vienna, on luminous bacteria.

As the paragraph in question is likely to give the impression that this is the first instance of anyone having succeeded in photographing the spectrum of these organisms, I trust you will allow me space in your valuable paper to point out that as far back as 1902, J. E. Barnard published an article dealing with luminous bacteria and containing, amongst other illustrations, one showing the spectrum of these bacteria with a hydrogen spectrum as control. (See "Nature," 1902, p. 536 to 538).

In the same article Barnard points out that the light emitted from these organisms is confined to a small portion only of the visible

spectrum (green and blue), and that it never extends into the ultra-violet or infra-red.

There is nothing new either about the photographing of a thermometer or any other article by the light given out by the luminous bacteria alone. Reproductions of some photographs have been published in dozens of scientific and other illustrated papers. A very fine example was printed in "La Nature," April 6, 1901.

If I remember rightly, the BRITISH JOURNAL printed during 1902, on two occasions, extracts from J. E. Barnard's papers dealing with his researches on luminous bacteria carried out at the Jenner Institute of Preventive Medicine, as it was then called.—Yours faithfully,  
12, Churchill Road, ALEX. CHRISTENSEN.  
Willesden Green, N.W.

[Reference was made to Barnard's work in our issue of April 18, 1902.—Eds. B.J.P.]

#### A DARK ROOM MYSTERY.

To the Editors.

Gentlemen,—Some time ago I fitted my dark room window with a "Geka" (flexoid) light screen, the flexoid sheet being supported and kept flat by a pane of glass. This particular dark room is used only for the purpose of changing plates, etc., and not at all for purposes of development. It is not in any way exposed to the weather, being built inside a chemical store-room, which latter, however, has no heating appliances, and so is apt to get rather damp during the winter season.

In course of time the flexoid buckled a great deal and contracted right away from the window rebates. At the same time the strange

sinuous white markings shown in the upper portion of the accompanying photograph made their appearance on both sides of its surface.

At first I was inclined to regard this pattern as the spoor of some insect or small animal that had used the flexoid as a pleasure. A friend who inspected the window expressed the conviction that the markings were due to a fungoid growth.

The other day I removed the flexoid sheet and submitted it to an examination. The white deposit constituting the markings was easily detached by gentle rubbing, and on examination under the microscope it showed no traces of a fungoid character. On the contrary, it dissolved very readily in water. This led me to suspect some volatile salt, such as ammonium chloride. I therefore added to the solution on the slide a drop of concentrated silver nitrate

solution. Contrary to expectation, large rhombic crystals (and not a white flocculent precipitate) almost immediately formed. This behaviour indicated the presence of a sulphate, an indication which was confirmed by the addition of barium nitrate and nitric acid to a fresh portion of the solution. The metal combined with the sulphuric radicle is evidently sodium, for the deposit gave a strong sodium flame, and neither the usual group reagents nor Nessler's reagent had any effect in its solution.

Remembering that I had preserved in the original package the surplus of flexoid over that which I had used for the window, I examined it and found that it, too, was covered with markings, which here, however, took the form of white star-like patches, such as are shown in the lower portion of the photograph. The flexoid had been wrapped in tissue paper, outside which came two sheets of cardboard, the whole being done up in brown paper.

The following questions suggest themselves:—

(1) Has any other portion of flexoid had a similar experience?  
(2) Whence does the deposit come? Is it an efflorescence from the flexoid itself or is it derived in any way from the wrappings in which it is sent out? (An aqueous extract of the tissue paper showed the presence of small quantities of S O<sub>4</sub>; I was unable to detect any thiosulphate in the extract.)

(3) Why are the markings on a sheet of flexoid, which has been exposed freely to light and atmospheric vicissitudes, of a totally different character from those which appear on flexoid which has not been so exposed?

(4) Have some of Mr. John Butler Burke's radiobes escaped and taken sanctuary in the dark room? DOUGLAS CARNEGIE, M.A.  
Blackheath, S.E.

#### THE COLOUR OF URANIUM-TONED IMAGES.

To the Editors.

Gentlemen,—Your footnote to Mr. Baker's letter in last week's issue, p. 398, has led me to make a few experiments on this point.

A 10 per cent. solution of pure uranium nitrate, and a 10 per cent. solution of pure potassium ferricyanide, were made up in distilled water and mixed in the following proportions, glacial acetic acid being added in definite and fixed quantity throughout.

Not having H. and D. strips of convenient size, a bromide print was cut into ten narrow strips, and each immersed in the solutions for five minutes, rinsed in water acidified with glacial acetic acid, and dried. The strips were not washed, so that no removal of the uranium deposit by our water (which is intensely hard) could take place.

The solutions were:—

	Uranium nitrate, 10 ccs.	Ferricyanide solution, 1 cc.
1.	10 ccs.	2 ccs.
2.	10 ccs.	4 ccs.
3.	10 ccs.	8 ccs.
4.	10 ccs.	16 ccs.
5.	10 ccs.	32 ccs.
6.	10 ccs.	64 ccs.
7.	10 ccs.	128 ccs.
8.	10 ccs.	256 ccs.
9.	10 ccs.	512 ccs.
10.	10 ccs.	

Each strip was immersed for five minutes. The colour increases in red with increase of ferricyanide, as proved by the strips which are herewith enclosed. I cannot conceive that the nature of the support, that is, paper instead of glass, can have any influence on the colour.

Mr. Baker states that "if the bath containing the excess of ferricyanide be allowed sufficient time to work, the colour of the negative is *precisely the same* as when an excess of uranium nitrate is present." Now, as my strips prove that with excess of ferricyanide the image is redder, it is obvious that a longer immersion, according to Mr. Baker, must produce a browner, that is a less red image.

I enclose also four bromide print strips, which were immersed in a bath of uranium nitrate, 10 per cent. solution, 10 ccs, ferricyanide 10 per cent. solution, 128 ccs, A for five minutes, B thirty minutes, C sixty minutes, D fourteen hours. I presume these times are sufficient.

The difference between A, B and C is certainly easily seen, the

being very much darker, but this is more particularly noticeable in those parts of the prints which were black in the original. Possibly, I should not say they were less red.

At the end of ninety minutes practically the whole of the uranium cyanide had precipitated, leaving the supernatant liquid very clear; still, D was left in fourteen hours, that is all night. The result is certainly darker, and the paper more deeply stained, but I do not call it less red.

Possibly you will give your readers your impressions of these strips. Your correspondent is dissatisfied with these tests and cares to try me with strips of negatives  $6\frac{1}{2}$  in. long and about  $\frac{1}{2}$  in. wide, I am pleased to repeat the experiments.—Yours faithfully,  
E. J. WALL.

In the first series of strips the colours steadily pass from brown to red. That treated in the No. 10 solution is yellowish brown, much paler, evidently as the result of bleaching by the excess of cyanide. In the second series treated for increasing times with solution No. 8 of the first series, that is, with excess of ferric chloride, the colour even of the strips longest immersed are distinctly darker than those of the first series treated with a solution containing excess of uranium. The strips do not confirm the experiments of Mr. Butler, to whom we have forwarded the examples for any comment they may have to make on them.—Eds., B.J.P.]

#### SULPHITES AND THE PYRO DEVELOPER.

To the Editors.

Gentlemen,—In the B.J. ALMANAC for present year, page 699, Thorne Baker gives a formula for a pyro developer, which highly recommends as giving the highest speed and gradation on rapid plates.

Now, while I hardly care to question the dictum of such an acknowledged authority, I must say that, to my mind, there are one or two objections to the formula in question. The proportion of acid is much too large, and the use of sulphite of soda as a preservative of the pyrogallol objectionable. As regards the former, the less the acid is neutralised in the mixed developer, especially the presence of so much alkali, but I would point out that this result in the formation of sodium citrate, in itself a powerful reducer. On the second point—and this view is confirmed by many practical men—I am bound to express the opinion that the use of such preservatives of pyro is a mistake altogether. When you make such a combination may work tolerably well; it is the solution has been kept a week or two that the great drawback is noticed. This is a more or less marked retardation of development, with, if the solution has been long kept, a difficulty in getting detail, the plate having the appearance of under-exposure. This points to the conclusion that while the sulphites undoubtedly retard the oxidation of pyro solutions, they also, in time, bring about some chemical change, which tends to retard development and the power of the reducing agent in producing detail.

In conclusion, I may add that a careful trial of Mr. Baker's formula on rapid plates has in no way led me to alter the opinion above expressed. To those who desire the utmost speed, combined with sharpness and gradation to be got with pyro, I would say always use a fresh solution if possible, or, if you must have a solution that keeps, nothing is equal, as a preservative, to metabisulphite of soda, in the proportion of one drachm to the ounce of pyro. More than this is unnecessary, and such a solution will remain good for a reasonable time without discoloration or undue protraction of development.  
H. C. PARLOW.

#### "PROFESSIONAL COLOUR PHOTOGRAPHY."

To the Editors.

Gentlemen,—I see in the BRITISH JOURNAL OF PHOTOGRAPHY of May 18, page 391, regarding "Professional Colour Photography," a paragraph where Mr. Otto Pfenninger claims to have opened a photographic studio for portrait colour photography in July, 1903. I do not see how he can claim this, for the following reasons:—In 1903, being short of Lumière B plates, and not having

the time to purchase the plates from my usual dealer, I called on Mr. Otto Pfenninger's shop in West Street (it being nearer to my laboratory) to ascertain whether he could get me some. At this time Mr. Pfenninger had certainly a good stock of all the leading plates and films on the market, but Mr. Pfenninger's knowledge of tri-colour photography was very slight, and he was very surprised when on other visits to his shop I showed him some of the results done by the then Jumeaux-Davidson three-colour process. He was at this time experimenting with a well-advertised three-colour process, but he very soon procured particulars of the Jumeaux-Davidson process and practised privately with it.

I frequently visited his studio, it being better adapted for portraiture than mine, in order that he should get a good set of negatives of myself in uniform (scarlet-blue colour test) for Dr. Jumeaux to experiment and obtain good results. This went on for some time, until we wanted more subjects (about July, 1903), when he procured some lady friends (including his wife) to pose for him as a favour, and most of these negatives were taken on a sliding repeating back, with occasional tests with a  $\frac{1}{4}$ -plate one-exposure camera for me. He exhibited in his shop window a few somewhat crude results in colours printed from the above negatives. This naturally caused some interest in the town, but I doubt very much if Mr. Pfenninger ever received a genuine order for a three-colour portrait up to the time he closed his establishment, when he came to me as assistant, or even up to the time I finished with his services.

I quite agree with Mr. Butler's answers to Mr. Pfenninger's letters published in your journal a few weeks ago.—Yours faithfully,

W. N. LASCELLES DAVIDSON, Captain.

(Late 4th Batt. "The King's.")

#### THE STATE OF WINCHESTER CATHEDRAL.

To the Editors.

Gentlemen,—Mr. A. Gandy, photographer, of Southgate Street, has to-day drawn my attention to the par. "Ex Cathedra" of the 18th inst., published in your JOURNAL OF PHOTOGRAPHY, as you state that the builders are at work on no part of the exterior and inside, the only portion to which their operations extend is the intro-choir (kindly note that presbytery is the more correct term). To take the exterior first. Besides the presbytery being propped up on its three sides, i.e., from the south transepts to the end of the building (and by July the east wall of the south transept will be in a similar condition), we have an awning of wood, supported by scaffold poles, over the west entrance. Most probably these supports will not be taken down for at least two years. As for the interior, your statement is quite correct as to the workmen being engaged on the presbytery only; but what does this phrase mean? That the Beaufort and Waynflete Chantries are covered up, including the Clobenay monument, Lord Northide, De Foix, Bishop Summer's cenotaph, the Ladye Chapel, Bishop Langton's Chapel, and the Chantry of Bishop Fox (partly exterior)?

Distant views of the Cathedral (S.E.) can be obtained from the entrance tower of Winchester College, and from St. Catherine's Hill (telephoto), and of the west front from the upper windows of Mr. A. Gandy's studio in Southgate Street, who has, I believe, already offered his services to the Convention, Winchester Cathedral and College, one of the three volumes of the ninety-nine view series, published by Messrs. Warren and Son, the High Street, Is., by post 1s. 3d., contains all the chief views of both edifices, and may perhaps be found useful as a guide to the visiting members of the Convention.

To show you the present state, both of the exterior and interior of the Cathedral, I have great pleasure in sending you a series of photographs recently taken by myself.—I am, Sirs, faithfully yours,  
28, Upper High Street, May 21, 1906. W. T. GREEN.

[We are obliged to our correspondent for correcting a statement made by us on the strength of particulars supplied to us from a quarter which we had reason to think was accurately informed. Mr. Green's photographs show the extent to which the scaffolding disfigures the Cathedral.—Eds., B.J.P.]

## Answers to Correspondents.

- \*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.**
- \*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- \*\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.**
- \*\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

### PHOTOGRAPHS REGISTERED:—

- G. A. Dean, 14, High Street, Rugby. *Photograph of Butler's Leap, Clifton Road Rugby. Photograph of Brage, Clifton Road, Rugby.*
- J. L. Hopper, 4, Fendle Street, Nelson, Lancashire. *Photograph of Tom Grave Flying the Revolving Wheel.*
- J. J. T. Glover, 124, Stephen's Green, Dublin. *Photograph of Football Team of 2nd R.I. Rifles.*
- A. Rollin, 1, Mayfield Road, Gosforth, Newcastle-on-Tyne. *Photograph of Fire at Saddler's Chemical Works, Middlesbrough.*
- F. Harle, 68, Manchester Road, Hyde, Cheshire. *Photograph of the Hyde Coal Pit.*
- H. Sartoris, Weekley House, Kettering. *Two Photographs of Rushden Hall, Northamptonshire.*
- A. Hinkins, Exchange Street, Retford. *Painting in Oils (Presentation Portrait), of Ex-Alderman Denman.*

I. R. CEDDES.—We do not happen to have any such memorandum by us. Any shareholder in a photographic company you may know will be able to get the memorandum of that particular association for you. Of course, the memorandums of different companies vary considerably.

THISTLE.—As we understand it, the screen of tulle is used on or near the hood of the lens, between lens and sensitive paper, i.e., when enlarging.

TONING WITHOUT GOLD.—Could you kindly tell me through your columns the method and formula used for toning p.c.'s the same as enclosed. I am told that no gold is used, but some sort of acid, and that from 300 to 500 p.c.'s can be toned for the cost of 2½d. Time also is claimed to be saved, and, as the results seem fairly permanent, perhaps you might throw some light on the matter.—POSTCARD.

We cannot recommend you to adopt any process of "toning without gold," for the alleged advantages are illusory. You probably refer to the simple and vile method of adding a little acid to the fixing bath. The results which are due to sulphur toning are not permanent. A better process is that on page 813 of the "Almanac," viz., fixing the prints first, well washing, and then toning in ammonium sulphide.

P. HENDERSON.—We should advise you to effect the exchange.

BARYTA COATING.—1. Will you give a formula for a baryta solution for coating postcards before coating with chloride emulsion? 2. Will the baryta solution require filtering, and what temperature should it be kept at for coating? 3. Are there any books on the above work.—J. HARRIS.

1. Hard emulsion gelatine 90 gr., sodium sulphate (not sulphite) 38 gr., water 5 oz. Allow the gelatine to soak for an hour, then melt in a water bath at 120 deg. Fahr., and add barium chloride 30 gr., water 2½ oz., stirring well. Allow the emulsion to set hard, and then break up into small pieces and wash for about four hours, then drain. 2. Yes, it is advisable to filter through fine linen or flannel, and the temperature should be about 100 deg. Fahr. 3. Possibly "The Photographic Picture Postcard," by Wall and Ward, might help you.

GODD HOPE.—We believe there is a paper published in South Africa. Apply to Messrs. Marshall, Brookes, and Chalkeley, Harp Alley, E.C. We can tell you that most of the better appointments in South Africa are filled in England through the shipping agents, and by advertisements in our columns.

WATER COLOUR FOR PHOTOGRAPHS.—I want to get some dry colours

of various tints, to use as water colours (mixed with water, etc.) for large-sized enlargements. Where I could procure such would ordinary painter's dry colours be unsuitable?—COLOUR.

Powder colours are supplied by all artists' colourmen. You must ask for them ground in water, not in turpentine. Ordinary house-painter's colours are useless for colouring photographs; they are not ground nearly fine enough for the purpose.

WITNESSES' FEES IN LAWSUITS.—I have recently taken photographs to illustrate points in a lawsuit. Then I understand I have to give evidence on in court. The case will be tried in London, and will mean practically a whole day off for me. Would you kindly let me know what is the fee I am entitled to charge for attendance at court (apart from taking the photographs).—LAWSUIT.

There are no recognised scales of fees for experts in law cases. They may range from a couple of guineas to fifty and upwards. These are usually arranged when the expert is engaged. In your case, we expect, you will only be called to prove that you took the photographs. You will get a guinea with the subpoena, and you should arrange with the solicitor for the side you go on as to what further remuneration you are to receive.

RETOUCHING.—S. B. D. (Liverpool).—Very good and long-exposed retouching. The man with moustache has the character and likeness excellently retained, and a difference in touch shown between the female and male studies—which is quite correct, and as it should be. The lady, however, has rather the appearance of "two lovely black eyes," and the depth of shadows might have been reduced with a more pleasing effect. When working a hard quality negative like the other man, make for a looser and more open grain, and a softer effect will result.

B. T. H. (Chatham).—If the bath is not overworked there is no reason why permanent results should not be obtained, even though it contains lead. We advise one without lead, just as we advise separate toning and fixing, but with systematic working the results should be satisfactory in either case. The formula for a bath without lead is:—Ammonium sulphocyanide, 15 grains; sodium chloride (salt), 30 grs.; hypo, 2 oz. water 10 oz. Add little by little, gold chloride 1 grain, water ½ oz.

RETOUCHING (E. E. L.).—Your work has improved so far, but touch and solidity are concerned, since last sending to us, your modelling is still defective. Two months is not a sufficient interval to show much advance. The nose is too flat, requires higher lighting to accentuate width. The chin, however, over-lighted, rendered smaller than natural, and upper curve is much too sharp and cut-out to be correct. Soften all edges, and respect the dimensions of the features, and you will improve considerably. For an eight months' retoucher you show excellent form, and should go far.

INDIA.—We have not examined one of these lenses, but we believe the range of equivalent focal lengths lies between 16 and 24 inches, requiring extensions of from 12 to 24 inches (back to ground glass). Major Puyo, in his book, advises the photographs to be used at an aperture of 1.20th the focal length. Apparently a less separation is needed. If you will let us see the lens we will advise you further.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

exhibition of photographs of flowers and domestic pets, by Stevens, will be opened at the offices of THE BRITISH JOURNAL PHOTOGRAPHY on Thursday next, June 7, and will remain open July 21.

series of novel photographs advertising the chief shops of Geneva been published by a photographic firm of that town. The book- which they are reproduced suggests similar opportunities for photographers able to produce photographs of advertising merit. (P. 425.)

publish a description of the San Francisco earthquake and fire the pen of Dr. d'Arcy Power, of the Western Journal, "Camera t." The illustrations are by Dr. Power. (P. 423.)

preliminary announcement is made of a new printing process, in which several pigment images are obtained from a bromide print out exposure to light. (P. 422.)

has been proposed to assemble professional photographers ending the Convention in July for a discussion of business topics. (P. 427.)

ractical methods in increasing sales, and questions which affect making of saleable portraits, occupied two speakers at the recent convention at Washington, U.S.A. (P. 427.)

simplified method of constructing hand-camera focussing scales is published on page 422.

brief account of the marine home of Mr. F. W. Speaight appears page 429 as an example of taste in interior design, for which Bond Street house of Speaight, Ltd., is noted. (P. 429.)

A paper by Messrs. C. E. K. Mees and W. J. Smith, before the London Camera Club, recently gave directions for the making of a photograph for use with a plate of given colour sensitiveness. (P. 430.)

A lamp for full length and bust portraiture and a new construction of folding cameras are among the week's patents. (P. 433.)

## EX CATHEDRA.

### A Photo-grapher Amid Earthquakes.

This week we are able to put before our readers the sensations of a photographer at the terrific upheaval of nature which in a few hours, directly or indirectly, destroyed a large portion of the city of San Francisco. Dr. d'Arcy Power, who is the writer, is known personally to many in Europe, and to a still larger circle through his contributions to the photographic press and his conduct of a department of the well-edited San Franciscan paper, "Camera Craft." We are sorry to hear that of the assets of the proprietor of that journal only the goodwill and copyright remain undestroyed. Printing plant and office equipment are gone in the ruin. What such a disaster means perhaps only those who have organised a newspaper office can properly appreciate, but no doubt our readers will join with us in wishing "Camera Craft" a speedy return to regular publication.

### Practical Fraternity.

Meanwhile, photographers in the United States are responding to the appeal for help for their 'Frisco brethren. New York professionals have contributed 670 dollars, those in the Rochester district 580 dollars, and the manufacturers have come down with donations of money and goods, the list being headed by the Eastman Kodak Company, which has delivered fifteen hundred dollars worth of materials and apparatus to San Francisco. These first fruits of an appeal to the photographic community are being steadily supplemented by donations accumulated by businesslike methods, and the total result, it is anticipated, will minimise the disasters to the photographic inhabitants of the Western capital. The victims of the fire, however, if they lack money, are not overwhelmed by their calamities. One man, with almost the humour of the shopkeeper who announced on the smoking ruins of his premises, "Slightly disfigured, but still in the business," writes that he has lost everything, including his books, but says he has still nerve to get another outfit and "go at it again." Also he sends to New York a ten cent piece for a copy of the "Photographer." It is a grim bit of humour. Imagine Birmingham in flames and a photographer forwarding twopence in stamps for his B.J.

### The Cape Town Society.

From every point of view, except the financial one, the recent exhibition organised by the Cape Town Photographic Society was held to have been completely successful, and it is therefore satisfactory to put on record that, by the efforts of the Society and the assistance of its friends, the deficit of considerably over a hundred pounds which was left at the close of the exhibition has been almost entirely wiped out. The report of a recent ordinary

meeting of the Cape Town Society suggests a very healthy condition of things. Accessions to the membership and to the life-membership are reported, and the support of many interested in photography is evidently being accorded to the executive, which is to be congratulated on having just acquired a new home for itself in the Old Town House of Cape Town, where a reading room and other facilities will be at the disposal of members.

### The Photographic Convention.

From the secretary of the Photographic Convention of the United Kingdom, Mr. F. A. Bridge, we are glad to hear that the prospects for the forthcoming meeting at Southampton are of that degree of brightness which should precede the celebration of the twenty-first anniversary of the Convention's inauguration. The Southern rendezvous—if we are to judge from applications for membership—promises to be highly popular, and to be attracting members whose faces have not been seen at Convention gatherings for some few years past. Indeed, the only cause for anxiety is likely to be the appropriation of accommodation for all those who will be in Southampton during the Convention week. The town, of course, has a large hotel service, but a good deal of it is naturally reserved for the passengers travelling by the liners. Hence the advice may be opportunely given to reserve rooms, and, at the same time, to notify the Convention secretary of intention to take part in the meetings. The task of providing for the wants of two or three hundred people is made considerably easier if the exact numbers are approximately known beforehand, and for this reason those who express their intention to visit Southampton will not only be doing the best thing for themselves, but will be oiling the wheels of the machinery which is to carry out the desires of the whole body of Conventioners.

### Business Matters at the Convention.

The suggestion conveyed through a letter from Mr. Bridge, which appears in another column, is one which we hope will prove possible of execution at the Southampton meeting. The photographic profession is usually represented by a number of men well able to discuss such matters of business importance as have occupied the conferences of their confrères in the United States, and even if the numbers which may be expected to take part in such proceedings is not as large as in America, it will be a good beginning for the Convention, and will lead to increased interest being taken in its programme. It is not to be expected that at such comparatively short notice the discussion of business topics can appropriate any considerable share of the Convention's proceedings, but we take it from the secretary's letter that a meeting might be arranged which would not interfere with the engagements of the main body of conventioners. At any rate, we hope that the suggestion will not be lost sight of, and that it may be kept before the Council of the Convention in arranging fixtures for another year.

### Carbon via Bromide.

Something of a sensation is likely to be created in photographic circles in the course of a month or more by a development in pigment printing, which owes its existence to Mr. Thomas Manly, the inventor of the well-known ozotype process. It is nothing less than a process by which one or more carbon prints or enlargements are obtained from a bromide without exposure to light, and without the intervention of a negative. The method, which is distinct from catatype processes, of which much has been promised, but by which, also, little in a practical way has been achieved, has, it need scarcely be pointed out, the very widest com-

mercial possibilities before it among professionals (more perhaps than among amateur users. Any notice of the principle of the process must be reserved for a more convenient occasion, as must also the announcement of commercial channels through which the process will be accessible to the photographers. We shall have more to say of the process the moment information is available for publication. Meanwhile these few facts will give readers quite sufficient food for thought as to the way in which such a process can be turned to profitable account.

### A GRAPHIC METHOD OF MARKING FOCUSSED SCALES.

THE ordinary methods of marking focussing scales are somewhat unsatisfactory when a scale showing a fairly close series of distances is required. It is seldom possible to mark more than a few near distances by actual measurement in the camera, while any method of calculation gives a series of small dimensions in fractions of an inch which cannot be readily set out. Perhaps the most usual method is to ascertain the infinity mark, and also the scale mark for some near distance, and then arithmetically divide the space between these two marks by observing the ratio of the scale distances from the infinity mark to different divisions are inversely proportional to the distances they represent. Under this rule a division halfway from the infinity mark to the 5ft. mark represents 10ft., while another at a third of the distance represents 15ft., and so on. This method has the defect that it only enables one easily to arrive at marks representing certain distances. Thus, in the case assumed, a mark representing any simple multiple of 5ft. will be readily arrived at, while other distances that are not simple multiples are not easily allowed for. It seems, however, to have hitherto escaped notice that there is a very simple geometrical solution

Fig. 1.

of the problem, and that the space on the scale between the infinity mark and any other mark representing a near distance can easily be so divided as to represent any required distance in feet, or even fractions of feet. The method is quite accurate in principle, and any error that exists can only be due to peculiarities of the lens. The procedure is as follows:—

First ascertain the infinity mark by focussing on a distant object. If the distance is 500 times the square of the focal length, the infinity mark can be fixed within 1-500in. of its true position. Next ascertain the extension of the camera beyond the infinity mark when focussing on an object at some definite small distance from the front principal focus of the lens, say, for example, 5ft. This gives the scale length from the mark representing infinity to that representing a distance of 5ft. Let this scale length be represented by the line AB in Fig. 1, A being the infinity mark and B the 5ft. mark. Through B and at right angles to AB draw the straight line CBD. Then take any convenient scale of feet (a small scale, such as 1/2 in.

16in. to the foot, is best), and from B to C set off a distance of 5ft., which is the distance represented at B. The figure, B C equals 5ft. on the scale of feet. Next draw C E, parallel to B A, and from A draw A E parallel to C B D. These two lines intersect in E, and they complete the geometrical construction. Now suppose we want to put a mark on the scale A B representing a distance of, say, 14ft. From C set out along the line C B D a distance, C F, equal to 14ft. by scale, and join E F. The line E F cuts A B in G, which is the position on the focussing scale of the mark representing 14ft. It is thus possible to represent any distance whatever, within reason, on the focussing scale A B, and distances less than 5ft. can be shown if A B is produced.

For very long distances are required it is most convenient to set them out, not on C D, but on a parallel line, half way between C D and A E. In this case, if an intermediate scale is used for C D a 1-16th scale should be used on the new line, H K, all measurements being made on H. If, however, two scales are not available, one may be used, the distances being halved along H K. For example, suppose we wish to mark the focussing scale 40ft. If C D is not long enough to permit a distance of 40ft., to be set out along it with a  $\frac{1}{16}$ th scale, we can either set out 40ft. on H K, with a 1-16th scale, or 20ft. on the line with the  $\frac{1}{8}$ th scale.

The advantages of this method of dividing a focussing scale are obvious. There are no troublesome calculations, and one is absolutely unfettered in the choice of distances, any one distance can be shown just as easily and accurately as any other distance.

By a slight modification, a diagram serving as a universal focussing scale adaptable to any lens is easily produced. In Fig. 2 the line C D is divided into a scale of equal parts representing feet, and from various selected points on that scale lines are drawn to the point E, which is situated vertically under C. To use this scale, find by

test in the camera the length of the focussing scale between the infinity mark and any other mark representing a near distance of, say, 5ft. Then tick off that length on the edge of a strip of paper, and lay the strip on the diagram parallel to E C, and with the infinity mark on the line E M (which is parallel to C D) and the 5ft. mark on the line joining E to 5ft. on the scale C D. One can then tick off on the slip the intersections of the various lines radiating from E, and mark the ticks with the distances given on the scale C D. A supplementary intermediate scale (constructed as before described) gives the distances from 40ft. to 80ft. In making such a diagram as this the exact distance from C to E is of little consequence. If

Fig. 2.

insufficient to admit the paper scale made in the camera, the dimension lines radiating from E may be produced upwards. The vertical dotted lines are simply to facilitate placing the paper slip parallel to C E.

By a further modification a scale of focal lengths can be added, and then, without any camera test at all, a focussing scale can in a few moments be ticked off that will fit any particular lens. This scale of focal lengths renders the diagram rather intricate, and introduces very minute divisions. It is extremely convenient for drawing a magnified focussing scale, but is hardly practical for a scale of actual working size, therefore it is not shown. Moreover, it is generally desirable that the limits of the scale should be settled by actual tests in the camera.

## THE DESTRUCTION OF SAN FRANCISCO.

SAN FRANCISCO, like most modern American cities, was a place of immense buildings. I am fairly well acquainted with the great capitals of the world, and there are few of them that could vie with her in beauty of site or in the imposing appearance of some of her architectural effects. Her great mansions, perched on commanding hills, backed by the setting of distant mountains, the great and beautiful shaft of the Call Building rising from the valley containing her business centre, and the enormous mass of the Fairmont Hotel flanking one of her best hills, presented an ensemble that, viewed from the heart of the town, was only equalled by some of the attempted reproductions of Imperial Rome. The morning of April 18 rose with all the placid beauty of a perfect spring day. I occupied my room on the fourth floor of one of the largest brick structures in the city, and was just about to arise, when, without the slightest warning, the whole house lurched violently to the north. Earthquakes are old acquaintances, for, though the newspapers seldom refer to them, no Californian is disturbed by seeing the chandelier swing; therefore, the first blow, violent though it was, did not alarm me. What followed no words of mine, or any human pen, can adequately describe. It seemed as though that massive building, containing over a hundred rooms, was in the hands of a colossus, who, holding it by the four corners, was wrenching it, first this way, then that, until it broke in pieces, as a man might tear apart a match-box. The walls rocked and crashed, the

floor heaved and buckled, the chandeliers and ceiling fell in on us. Time is a question of relation. There are hours that pass as minutes, there are moments that grow to hours. For sixty seconds, an eternity, that fearful movement continued, accompanied by a pandemonium of sound that haunts me still. To the roar of the earthquake, like to that of a mighty wind, was added the crash of hundreds of tons of masonry. The three storeys above my head, separating at the line of my ceiling, were hurled into the street below; the immense dome, the mighty pillars, and all one side of the great City Hall (a pile larger than Westminster Abbey) fell in thunder to the ground; two brick apartment houses, of many storeys, crashed into a heap of debris before our eyes. Not even the thunder of a bombardment can approach the terrific effect of that awful crash. It was useless to move. We lay silently awaiting the death that seemed inevitable, when, suddenly as it had begun, the earth rested in silence. Seizing some scant covering, we rushed through escaping gas, clouds of plaster, and streams of water, into the street. The debris of the upper floors lay piled across the road, covering the bodies of two it had overwhelmed. The ground was dangerous with broken electric wires; and through the air, dim with the dust of fallen palaces, the skeleton frame of the great dome hung awry, an embodiment of the universal ruin. I had no camera to record that first terrible impression, and it is doubtful whether any record was made; yet few

subjects could offer a more dramatic field for a great artist than the wreck of that mighty building standing in its yellow cloud of dust against the tender blue of the opening day.

Such was the great earthquake. As we sought safety in

Effects of Earthquake on the City Hall, San Francisco.

another part of the city we had an opportunity of observing its effects. These varied greatly, in accordance with the character of the buildings and the local nature of the earth. Thus wooden frame buildings never collapsed, unless they stood

The newly constructed buildings made of steel frames covered with bricks were generally unaffected, and no greater testimony to the value of this mode of construction could be afforded than the great tower-like structure of the Call Building standing erect and perfect, 270 ft. above the street. It was the plain brick buildings that suffered the most. In many cases they collapsed entirely; in others, owing to the direction

A Common Street Scene in San Francisco after the Earthquake.

the force, the north and south walls fell out, leaving the floors in position. Brick cornices almost invariably fell, and often carried the supporting wall with them. Examples of these effects will be found in the accompanying illustration. If the effect of the earthquake on the buildings was remarkable, it was no less so on the solid surface of the earth. The crust, including the rigid surfaces of the streets, moved

Four Square Miles of Ruins—San Francisco after the Disaster.

on piers rotten with age, when in some cases they broke up into masses of kindling wood; these buildings usually have brick chimney stacks, and these were invariably thrown down, often passing through the roof, and doing great damage.

billows like those of the ocean; and there are regions in the city where the ground did not return to its original even surface, but remained like a frozen sea, rising in hummocks and broken by deep fissures. The earthquake

ruined all, it terrified many, and it killed a few; but, taken as a whole, the direct loss in lives and property was not so great. Had nothing else occurred, we should have rebuilt new structures, moved out of old brick buildings, and gone on as usual; but, before ten minutes after our escape from the wrecked building, I looked over to the south side, and there five columns of smoke ascending. The conflagration had begun. This caused neither surprise nor concern, as the department of San Francisco is one of the most efficient in the world. That the fires would be out in an hour was the usual expectation. Alas, within an hour the five isolated fires were a devastating wave sweeping southward before the wind like a prairie fire and creeping northward like a glacier. The earthquake had destroyed the water mains, and the fire department was powerless. Then followed confusion, panic, and destruction. The fire department could use dynamite, but not dynamite. Tinkering, spluttering attempts were made to check the advancing ruin, but no organising, no competent head guided the use of the only agent that could have saved the city. It would have been, in the early hours, easy to isolate the advancing fires by cutting a broad area of destruction across their path; and, unfortunately, such a course saved the remnant now left standing, but it required the bitter experience of two days to discover that fact.

During the first day houses were blown up here and there, usually after they were in flames, and the dynamite never aided than checked the destruction. From the roof of a house on a high hill in the centre of the town I watched flames spread in a mighty crescent over two miles from tip to tip, and sweep back to the bay, licking up like dry grass the homes of thousands of working people, who trudged wearily on with little or nothing. Hour after hour the long procession streamed countrywards, a depressing and melancholy sight. Then the two horns of the crescent struck northwards towards our place of refuge, and we were compelled to move

farther west. Before I left, I saw the house I dwelt in go up in flames, and with it most of my property, all the results of my labours in photographic art, and over two thousand negatives. I went to the house of a medical friend, and spent the night in watching the advancing fire, and in comforting the sick that had been transferred here from his sanatorium.

Towards five o'clock in the morning the fire was again near at hand, and we were compelled to take final flight from the ruined city. Like thousands of others, all my property, including the art accumulation of years, had gone in the flames. That morning the beggar and the millionaire met on common ground: they alike had nothing.

For yet two nights I watched from my country house, twenty miles away, the glare of the fire, and constantly picked up fragments of paper carried that distance by the wind. Over all that area, and farther, the ashes descended in quantities sufficient to whiten our roofs. Such was the burning of San Francisco!

Viewed as photographic subject matter, it was too large for adequate portrayal. The lines of fleeing people, the scenes of activity around the burning buildings, were, on the other hand, the very best of material for the clever snap-shooter. How far the opportunity was utilised I am, as yet, unable to say; most of us were too deeply concerned in saving our families or property to give much heed to the greatest photographic opportunity of our lives.

If the fire, as fire, offered little to the photographer, it gave to the painter lessons in colour and aerial perspective such as yet has never appeared on canvas. As that vast mass of smoke and vapour rose through the singularly pure atmosphere of a lovely spring day the sun gradually took the aspect of the orb when viewed through smoked glass. Finally, about mid-day, a most remarkable appearance presented itself. The solar disc assumed a tint of the most violent red.

H. D'ARCY POWER.

## A TOWN'S PHOTOGRAPHIC ADVERTISING.

I have spoken on several occasions of the photography which is now done for advertisement purposes, pointing out that such appli-

graphic matter with greater freedom in their announcements, usually combining the photograph with artist's line or wash drawing, by

At De Bay's (Articles of Toilet).

A. Wallner-Muller, Optician.

tion of photography is greatly on the increase, and represents, at present, a remunerative field of work. Every month sees the chief advertisers in the large weeklies and magazines using photo-

contrast with which greater strength is given to the subject proper of the advertisement. One objection which has been urged by photographers to whom such work has been recommended has been

the very legitimate one that it was extraneous to their business, and while it might put a few pounds in their pockets from time to time it did not in any way help along their regular profession in their town of residence, and for this reason might cost them more

au Maison Bertrand.

than it brought in by diverting their energies occasionally into other channels.

Those holding this view may be glad to have their attention drawn to the scheme of a Swiss photographer, Mme. L. Fueslin-Rigaud, of Geneva, which should handsomely repay the photographer for his work, and at the same time be the means of making him widely and favourably known in his town. The essence of Mme. Rigaud's plan, which possibly may have been carried out in other places, is a booklet of about twenty pages, advertising indirectly and in an uncommon way the principal shopkeepers of Geneva. The booklet contains letterpress and half-tone illustrations in equal proportions, is well printed on art paper, and is, we presume, distributed free for the photographer. The outside cover bears no indication of the very commercial mission of the publication.

It is entitled "La Rève d'Yseult," and the letterpress recounts in very readable fashion the dream-experiences of this young lady, in the course of which she has the gratification of visiting a selection of leading shopkeepers in Geneva, and purchasing necessities and luxuries befitting a lady who dresses well and has a fine house. Thus, Yseult soon finds herself at the confectioner's (Maison Finay), where she partakes of ices and purchases chocolates, whilst an elegant gentleman engages her in agreeable conversation. The need of

articles of toilet brings her to De Bay and Co., whose establishments and specialties are the subject of an appreciation by the writer of Yseult's adventures, in accompaniment of the photograph by Mme. Fueslin-Rigaud, which we reproduce. In the evening Yseult is to occupy a box at the opera, preliminary to which a call is paid at the opticians for lorgnettes for herself and a pair of glasses for her companion. The imaginary incident elicits the information

Shopping at Badan & Co's.

that the optician, Wallner-Muller by name, offers a discount of 10 per cent. during the Christmas shopping season. Thoughts of feminine attire which come to Yseult in her dream transfer her to the corsetier, from whom, to her delight, she is able to obtain a corset which gives her no discomfort in moulding her figure to the fashionable shape. Silks and frou-frous of the "dernier chic" are likewise sought by Yseult at the firm of Badan and Co., and so, altogether twenty-four establishments she satisfies the cravings of a modern woman and provides herself with innumerable good things to eat, drink, and wear upon her person.

The four photographs of this series are reproduced by permission of the successor to Mme. Fueslin-Rigaud, M. Louis Minner, Cours de Rive, Geneva, by whom the issue of another booklet on the lines of "La Rève d'Yseult" is in preparation. As may be judged from the reproductions, the quality of the photographs is of the somewhat high standard required in prints intended for advertising purposes, and it is noteworthy that many of the subjects might be used for other advertisement purposes than those for which they were originally taken. In more ways than one, therefore, the producers have profited by their enterprise, for the booklet, with its twenty-five attractive photographs, has no doubt benefited the business of those responsible for it as much as it has the various firms to whose goods attention is drawn in its pages. It may, perhaps, be of service to some of our readers if we mention that M. Minner is open to accept an offer for the right to reproduce the series in Great Britain and the Colonies, an offer which might easily repay advertisement agents and others able to place the photographs in suitable quarters.

**SOUTH Essex Camera Club.**—Mr. Walter D. Welford, President of the South Essex Camera Club, will conduct a party to Belgium in August next at an inclusive cost of £6 only. Arrangements are also made for single week trips.

**PHOTOGRAPHIC Picture Postcards.**—Of late it has not been an uncommon thing for a householder to be approached by a photographer's agent with an offer to photograph his house and reproduce it in the shape of picture postcards. This demand for private picture postcards, if new, is a growing one (writes the "Daily Mail.") The London Stereoscopic Company, of Regent Street, is experiencing it, and, apart from the thousand or so copies of a country house ordered by estate agents with a view to business, not infrequently gets orders for smaller numbers from private individuals. Many ladies have ordered photographs of their pet dogs to be reproduced as postcards,

which are sent to their friends. Photographs of private individuals are also treated in this fashion. The cost for these hand-printed cards in the bromide process is £5 5s. for 500, including the sitting. Now that sensitised postcards can be obtained for 1s. a packet at any photographic dealer's, hundreds of amateurs print from their own negatives. Many professional photographers take a portrait and reproduce it as a postcard at the rate of 3s. 6d. a dozen.

**THE Borough Polytechnic Society.**—We are asked to state that the present secretary of the above society is Mr. W. F. Harrap, who has succeeded Messrs. Francis and Wynne. The society's address is 103, Borough Road, London, S.E.

**THE late Mr. Matthew Boak**, of 66, Lyell Street, Scarborough, Yorkshire, retired photographer, and formerly in business in Bridlington and Driffield, left estate of the gross value of £6,486.

## BUSINESS TACTICS AND SALEABLE PORTRAITS.

(Two Papers read before the Washington Convention of the Photographers' Association of Pennsylvania).

trouble with many photographers of the better grade (and those who attend conventions belong to this class) is that we are poor business men, or, what amounts to the same thing in the end, is that we do not give the business end the attention that we should.

Sometimes we allow outside matters to dominate our attention to the detriment of our business; when this is the case, we should as soon as possible draw out of this condition of things. Again, with those who make their own sittings, and do much other work of the studio, it is hard to find time to develop the business. The economical employment of time, our own as well as our assistants', with a good system of accomplishing this, would largely help to get some time each day to give to this matter. If we employ assistants, then it should be easy of accomplishment.

### Offer Something Better.

One very good and impressive way to increase sales is by the work we produce, and if care is taken and good judgment displayed, it could be most effective. When you have patrons who are able to do anything in reason for worthy things, arrange to make different sittings in addition to what they desired in the first place, but make them "winners"—something that will be sure to please. They may, in the first place, have thought only of having work of the value of ten or twenty dollars, or even a smaller amount, to fill a want for photographs that has come up. It rests with you in addition to the supply of this demand, to enthruse them by the result of the sitting, as shown by the proofs submitted. When finished with them in the studio—and this should be done within a reasonable time—tell them that you would appreciate it greatly if they could call in the next day, for you would like to look over the proofs with them. Mention to them that you have in addition made something a little different from what they desired, because it appealed to you as presenting great possibilities, and you would in consequence like to see how they come out. Do this, and if you are personally a good salesman you will get the goods; if not, let your expert receptionist do so. Everyone likes to receive personal attention, and everything that savors of it, especially so if it impresses them that it is unusual on your part. By this means, you see them first when they receive the proofs, which is always an advantage, as you have an opportunity to adjust any adverse opinion as to their merits, before their friends have possibly raised a feeling of dissatisfaction, which is hard to eradicate. It also enables you to coach them as to what changes could be effected to improve them, which information could be conveyed by

them to those who sit in judgment over the results of your labours. In this connection, I am strongly inclined to think that it is inadvisable, when a would-be patron comes to our studio to make an appointment for a sitting to do anything more at that time than to show her an assortment of interesting things, leaving the matter of final selection and the exact decision to be made later.

### Make Sales at an Interview.

In a general way, if information as to prices are asked, quote them clearly and carefully so there will be no misunderstanding come up, or the integrity of the studio questioned. When the patron comes to fulfill the engagement, ascertain her wishes, secure your deposit, and arrange if possible to have them bring in the proofs, at which time only should sales be made. If this cannot be done, then make the sale at the time of sitting. Results are always most successful by personal intercourse when the proofs are returned, otherwise you endanger the success of your "building methods" in the studio.

I mentioned, a short time ago, about having the patron come in next day to look over the proofs with you. If possible, make an appointment with them for the purpose, say from 4 to 5 or 6 p.m., when the sittings for the day are over, and let this hour or so be devoted daily towards increasing your output. This would be one of the directions in which it could be done, being the simplest, most effective and economical. I often hear of patrons coming to a studio and not being able to see the proprietor because he is busy developing, —a most ridiculous state of affairs, neglecting something that might increase his sales for that which could be done at another time.

If you have a tactful and efficient saleslady, your presence will not be asked for, unless important. Do not 'phone down stairs "that you cannot come, as you are busy with your chemicals," etc.

One of the most successful men in our profession to-day—one who is also famous as a workman—has for years made it a point to be at his studio certain hours the later part of the day. On one occasion when in that city for a day, I went to his studio about 5 p.m., to talk with him prior to a dinner appointment we both had. While waiting for him to be at leisure, I saw him angling, and finally securing an order for a large picture and frame for \$150 from a customer who called to see him by appointment to talk over his sitting of the day before.

This is the result of a system founded on good lines. With a haphazard way of doing things, the proofs might have been mailed, and my friend might have been developing. The opportunity for which he planned would then have been lost.

CHARLES WESLEY HEARN.

### SALEABLE PORTRAITS.

offering my service to you on the subject of saleable portraits, I would divide the photographic trade into three groups or classes: The impressionistic man, the modern photographer, and the conventional photographer.

Now the question is, which of the three groups or classes of photographers are the most successful ones from a business standpoint of view? By analysing their conditions, we will see that in each group there are some more successful than others, inasmuch as they have different ideas as to what should be offered to the public. While one class photographs—plain and simple—and gets the trade, another combines art with common sense in his work and sells his pictures, and the third one produces pictures of a high æsthetic and pictorial conception, and also sells them. We will not discuss the last-named photographer for the time being, but will take up the former two, and, in speaking of them, we will see that next to the quality of work they produce, nothing is more essential than the manner in which they display the work to the public. The display in their show-cases is a very important matter, and in this connection I would say there are a great variety of methods.

Very often we find among the conventional photographers the same kind of pictures displayed in their show-cases year in and year out,

and if it happens that they do make a change, the styles of the pictures are the same. He has fallen into a rut, and digs on day by day in the same way, and if you should comment on it he usually confronts you with the reply that times are hard, he has no money to spend on improvements; little thinking that with improvement in the treatment of his customers things in general would be bettered. While in other places you will find all the latest processes employed, and displays of a large variety of work on view to the public, something, in fact, to please everybody. It makes but little difference as to the size of your show-cases, keep your display down in number, but high in quality, and change often. The public at large are attracted by tasteful displays in your show-cases.

### The Show-case Inducement.

When you exhibit only a few pictures at a time, it stands to reason that when a change is made it is all the more noticeable. Another important item is that you should have your studio just as tidy and as neat as you can make it, and your show-case should be so arranged that the public will become fascinated by it, and to such an extent that they will venture into your studio, and your opportunity should then begin; as we all know, human nature requires

some coaxing. The best method to pursue is to study your patrons and get an idea of their tastes and their ideas, and then put the proper pictures before them in the proper manner. We have all found in our experience that prospective customers are not always decided as to what they want, and yet they are willing to spend a little money. Therefore, the next important thing for us to do is to employ the services of a good receptionist. To sell pictures is a born tact, and not one that is easily acquired. You cannot use too much care in the selection of your receptionist for the simple reason that, if a mistake is made in the lighting or posing of your sitter under the skylight, there is a remedy, of resitting; but, if a mistake is made in the handling of your patrons in the reception room, and they are allowed to leave your studio dissatisfied, there is no remedy. The incident is closed to the detriment of the business. In view of these facts you can readily realise that it is of vital importance to have a qualified receptionist.

### A Protest Against Cheapness.

Charge all your work is worth, and always strive to improve the quality of it, and to see how good and not how cheap you can sell pictures; for the public to-day stands ready to pay more for good photographs than ever before—as its taste has become more cultivated. Put as much energy in your work as you can, thus advancing the standard of same, and do not try to outbid your competitor in low, ruinous prices. Following out this course your success will be assured.

I feel quite positive that here among us there are photographers who started to make pictures at about \$3.00 per dozen, but by diligent application to their chosen vocation are to-day, perhaps, among the honoured and successful ones in the profession, and who are obtaining prices as high as the highest for their pictures. To such men is due the highest respect, for it was through their continued effort to the betterment of their work, and also through the love of same, that has crowned them with success, for no man can do justice to himself and his work unless he loves it.

Now let us take up the photographer himself, taking for granted that his shop and his personal abilities work in harmony with his reception room. We are now entering the place, where he gets results—and how he pleases his patrons. We must admit that manners and good tact are very desirable factors, yet the desired results cannot be obtained with them alone, but they must work in conjunction with his camera and the subject before him; he must carry out all the promises made by his receptionist.

Treat your sitter under the skylight in a most natural and simplified manner; use the simplest means of lightening or posing of the subject, and arrange the lights in a most unpretentious way, and at the time you make your exposure see that their faces have the most pleasing and natural expression. In other words, they should be absolutely relaxed at the time you expose your plates—and this is just what will please your patrons at all times. It is quite natural that your sitters do not always bear the same expression in their faces, therefore if we produce a picture that represents their most pleasing attitude, their most natural expression, we have given to them something that will always appeal to them, as it is human nature to want to be pictured in the most pleasing manner, and if you have succeeded in gratifying that desire they will advocate your work to their friends, and in that manner you convert your patrons into agents who will work in your behalf and make you popular, which is an incentive to prosperity, and you can then gradually increase the sale of your pictures by securing the confidence of your patrons, which is absolutely necessary for our existence—thus is the way to ascend the ladder, and there is always room at the top.

### The One-man Studio.

Now a few words about the impressionist. While he stands in an entirely different class by himself, it would hardly be necessary to analyse his peculiar condition in the way of selling his portraits. He enters into our profession as a dilettante, and, being an amateur, he learns to do things in his own peculiar way. He is a man of culture and refinement, and, above all, he is gifted. He takes up photography as a hobby, combines in his pictures all the artistic and æsthetic elements, he exhibits those pictures in various salons, acquires recognition, with the following result. His friends begin

to coax him to photograph them and they are willing to pay the price he puts on his portraits. He doesn't need any receptionist, display, or shingle at the entrance. You will find him in a quiet quarter somewhere in the skyscrapers or on top of the stairs or on the skirts of the city, having his shop in a most unique way, making portraits at an ordinary window. He employs no help, has had no expensive worth while speaking of, does not seek popularity. In fact, he plays more than he works, and produces results which humble professionalists are looking up to as towards a Mecca. Most of them don't depend on photography as a means of a livelihood, yet while the demand for their work increases among their friends, they are compelled to become professionalists. While their pictures are peculiar ones, they still have the feeling of fine art, and we are amazed to see what wonderful things are created by them to-day. They only sell single pictures to their friends, and procure high prices for them. While they are new in the photographic profession, I foresee the greatest material success for them in the near future, inasmuch as from an artistic standpoint their pictures are fit to be purchased at any price, not only by the subjects themselves, but as masterpieces.

### A Commercial Fusion.

While it is true that the taste of the public has been developed, it has not developed to such an extent that the art and the value of the impressionistic photographer is yet fully appreciated. There is a demand to-day for a kind of picture which merges those two peculiar extremes—the conventional photographer and the impressionistic photographer. Therefore, modern photographers, from a business standpoint of view, must have the same essential system as the conventional photographer, namely, the display at his entrance, the specimens in his reception room, and the salesmanship. He produces, he makes pictures which, photographically speaking, have a sufficient amount of technic, and yet are of such high refinement that it puts them in a class by themselves.

### The Modern Photographer.

Let us take a peep into the method of how the modern photographer sells his pictures. We know that he is a technical man. He can at any time make good ordinary photographs. He is the man who never fails to attend the convention; he never misses an opportunity to visit an art display of paintings and engravings. He is the man who subscribes to photograph magazines, reads them, too, which is a very important feature; he visits his competitors, never asks what developer is used or what plate is used, never pries into the secrets of another man's formulas. Why? Because, he has a good intuition and grasps things at first sight. When approaching his patrons he is not simply polished in his manners, but he makes you feel that he is a man who always deliberates before he starts on his work. That intelligence you can see in his establishment. He does not buy a thing simply because Mr. So and So uses it, or because it is a novelty; he does not change mounts according to the seasons, nor does he fancify his works. He is an earnest man and gives his patrons all the benefits of his intelligence. He very seldom submits to the taste of his patrons, unless they are essential to him or experimental. In other words, he is honest to himself, he makes things the way he likes them, and not the way the public demands them. He is the master of the situation, and while most of them have originated from the rank and file, to-day they keep in the profession that standard which is envied by the conventional photographer. That class of men, outside of selling their pictures at a profit, is growing in the profession. They are becoming leading men in their cities, not so much in wealth, but as professional people, because the conventional photographer is simply a tradesman, the impressionistic man is an artisan, and the modern photographer is a professional man.

### Capitalist Photographers.

In direct opposition to the cheap John picture seller are the capitalist photographers who go about from town to town; they cover the country and have established a chain of studios in leading places, investing large amounts of capital in opening elegant studios, putting up elaborate fronts, attracting the public by their immensity. They have in their reception rooms the most cunning saleswomen,

are wide awake. These capitalist photographers invite visitors to their studios constantly, aim to interest society folks, universities and lodges by offering pictures gratis, and then build their trade on these schemes. While their work is absolutely conventional work,

still they have the knack of presenting the picture in a striking manner, which appeals to the public. Nevertheless, while this class of photography is making a sensation among the public, the quality of work won't stand the test of time. ELIAS GOLDINSKY.

## THE HOME OF F. W. SPEAIGHT.

Bond Street, as everybody knows, the firm of Speaight, Limited, has built and furnished for their photographic business of child portraiture an establishment which cannot be easily over-described. "Palace of art," which was a term freely applied to the suites of reception halls and studios at the time of the opening of the premises, accepted without reservation by a visitor who is fortunate enough to have the opportunity of making himself acquainted with the beauty and harmony of the design and decorations. In every detail of the apartments, galleries, and stairways carry out the aim of the firm: to provide a home for their business which should

constant study, and his home at St. Margaret-at-Cliffe, near Dover, equally with the Bond Street house, is evidence of the success which waits on the patient and sympathetic labour which everyone may be expected to exert in the beautifying of their homes, though few may possess the intuitive sense which saves them from making bad mistakes. "The Corner Cottage," as the house is called, overlooks the tiny bay of St. Margaret's, and is built so that all its windows, except those of the offices, overlook the sea. The design of the exterior and interior is that of an Early English cottage, being entered through an enclosed porch, shown in the illustration on the left. The large entrance hall, placed in the centre of the

The Corner Cottage, St. Margaret's-at-Cliffe.

The Entrance Hall, The Corner Cottage.

impress the visitor, not as vulgarly rich and costly, but good and substantial and in the best of taste. The result of a plan conceived on these lines can be seen in the reception salons of the Speaight house. What is not seen, but is equally a factor in the firm's success, is the similarly assiduous attention to important details in the workrooms and other parts of the premises where the actual production of photographs is performed. Here, as in the public rooms, initial expense has not been spared to provide things so that the machinery of the business shall work smoothly, and the staff of assistants have everything to aid them in their work. It is no doubt known that for these successful designs Mr. F. W. Speaight is chiefly responsible. The Bond Street establishment represents in fact his ideal of what a photographer's place of business should be, and the success of one, therefore, who is content to call himself an amateur in architecture should encourage photographers generally to think more of matters of appearance in the arrangement of their premises. With Mr. Speaight architectural design, particularly of interiors, has been a

house, admits to the sitting room hall, round three sides of which runs a gallery reached by stairs within the room. A dining parlour, study, kitchen, and other offices are upon the ground floor. In the arrangement of these rooms, as well as of the bedrooms and servant premises, convenience as well as comfort has been studied, and quite a characteristic note of the designer is struck in the statements that "the house can be well managed by two servants, owing to a large extent to the great care shown in the planning of the domestic offices to save work," and that "the gardens are kept in their present perfect state by a man one day a week." The gardens, it should be added, are the completing surrounding of a delightful old-world residence. Clipped hedges, an old Marcus stone seat, yew paths, a trellis arbour, combine to provide a perfect setting for the house and the means of quiet enjoyment. The Swiss proverb, "To those whom the gods love they give a house in Zürich" might appropriately be modified to represent the favoured ones as dwelling above St. Margaret's Bay, and in such a house of ease as that in which Mr. Speaight has made his home.

THE Bristol Photographic Club have started a magazine, the chief aim of which appears to be the keeping of all the members in good spirits by the administration of plenty of good-natured chaff. The magazine has its serious pages, and then is dreadfully in earnest as to folios, art, and other matters. In its lighter moods it should achieve much towards the prosperity of the Club.

MESSRS. John J. Griffin and Sons, Ltd., announce their willingness to send a demonstrator to any photographic society, giving a lecture on their new Goldona paper, during the summer months. This lecture is likely to be of interest, as it deals with the theory as well as the practice of self-toning papers, and contains matters perfectly new in this respect. There is, of course, no charge to the society.

## ORTHOCHROMATIC PLATES AND FILTERS.

(A Paper Delivered at the Croydon Camera Club, May 16, 1906).

THE introduction of new colour sensitive plates has necessitated readjustments in three different branches of photography—in orthochromatic photography, tricolour photography, and in tricolour half-tone. In this paper we propose to present to you the result of our investigations so far as they concern orthochromatic photography; a research into tricolour screens is already in progress of in our laboratory, while the application of the plates to three-colour half-tone has been worked out at the L.C.C. School of Photo-engraving at

ness of the pinacyanol bathed with the green sensitiveness of the verichrome.

### The Light Filters.

We have made for these new plates three yellow filters. First, a light yellow filter such as is usually termed an eight or a ten times filter; this requires about twice the normal exposure on the new plates. Second, a yellow filter which gives practically perfect colour correction for landscape on the verichrome and for all colours, includ-

Fig. 1.

Fig. 2.

Bolt Court. These investigations will shortly be published. The experimental methods which have been used are simple. They include exposures in the spectroscope to the standard artificial daylight designed by S. E. Sheppard and one of us, and the measurement of the densities so obtained. (PHOTO. JOUR., March, 1906). It must be noted that in this work daylight and a grating spectroscope have been used throughout, since much better, but totally misleading, results can be obtained by the use of artificial light sources or prismatic spectroscopes.

### New Colour Sensitive Plates.

The four plates with which we are at present concerned comprise the "New Verichrome" sensitive to 6,000, the "Pinachrome Bathed" sensitive to 6,200, the "Pinacyanol Bathed" sensitive to 7,000, in the red, but weak in the green, and a new plate which has been named the "Wratten Panchromatic," and which combines the red sensitive-

Fig. 3.

Fig. 4.

ing red, on the "Wratten Panchromatic." This screen requires about five times the normal exposure. Third, a "luminosity" filter which gives a luminosity curve on the panchromatic, by which perfect rendering for the most difficult picture copying can be obtained. This filter requires eight times the normal exposure.

### The Spectrum Curves of the New Plates.

These are shown in the figs. 1 to 5. Of these fig. 1 is the curve of an ordinary plate, the "Wratten" ordinary. Fig. 2 is the "Verichrome" plate. Fig. 3 the "Pinachrome," Fig. 4 the "Pinacyanol," Fig. 5 the "Wratten Panchromatic." In each case the curve which is lower in the blue represents the effect of the No. 1 yellow filter in cutting down the blue and violet.

### The "Luminosity" Filter.

The method by which this filter was obtained is as follows:—The curve of the Wratten Panchromatic was first measured and is shown

Fig. 5. Together with the spectrum plate there was developed a curve which had been exposed behind the sector wheel, thus giving connection between the density obtained and the light incident. Interpolating the densities of the spectrum record upon this curve

Fig. 5.

Fig. 6.

Fig. 7.

may obtain a record of the equivalent intensities incident. Thus 5,500 the spectrum record gave a density of .444. From the sector wheel exposure .244 corresponded to an exposure of .632 candle metre seconds, and .584 to an exposure of 1,264 candle metre seconds,

consequently a density of .444 corresponds to an exposure of 1.02 candle metre seconds, which is recorded for 6,300.

This curve is shown as the solid curve in fig. 6.

Now to give the luminosity curve. The blue part of this plate curve of the Wratten panchromatic was first measured and is shown the light, at each wave length, must be divided by an amount found

Fig. 8.

by dividing the height of the solid line by the height of the dotted line. This process gives the screen required, and the densities of the screen are shown in the solid line in fig. 7. Two screens were then made to this curve, the one, the No. 2 filter, and the other, the No. 3, or "luminosity" filter. The screens were made by adjustments of the dyes in the spectrophotometer to fit the curve, and then were prepared as gelatine filters.

The curves of these two filters are shown in fig. 7, and the effect of the "luminosity" filter upon the Wratten panchromatic is shown

Fig. 9.

in fig. 8, where the slight drop at 6,100 due to the plate is distinctly visible.

#### The Exposures Required with Filters.

In order to find the multiplying factor of these filters for black and white subjects, the sector wheel exposure instrument was fitted with a filter so that the upper half of a plate is exposed to light which misses the screen, while the light reaching the lower half passes through it. Fig. 9 shows one of these plates, and the ease with which the increase required can be read off is obvious. The multiplying factors for the three filters are, as stated, two, five, and eight.

C. E. KENNETH MEES.

W. J. SMITH.

## THE NORTHUMBERLAND AND DURHAM FEDERATION.

THE following is the fourth annual report of the Northumberland and Durham Photographic Federation:—

During the past year one new Society has joined the movement, and two have left. The Federation now consists of thirteen societies, with a total membership of about 650.

The thanks of the Federation are due to those gentlemen who kindly consented to lecture without fee or reward, and who enabled your Council to submit a lecture syllabus of sixteen items to your societies. This is a decrease of eight items as compared with last year.

During the past season a federation class was held at one exhibition, Tynemouth.

The annual reunion, which took the form of a dinner, was held at the County Hotel, Newcastle-upon-Tyne, on March 14, and was a decided success, sixty-six persons being present, including the guest of the evening, Mr. A. Horsley Hinton, and the Mayor of Newcastle (J. Baxted Ellis, Esq.). The President (W. S. Corder, Esq.) opened up the question of the various societies taking a co-operative interest in a photographic record and survey of Northumberland and Durham. It is hoped that the Federation will give this matter their consideration.

The Federation Lantern-Slide Competition received twenty-four entries; the slides were judged by Messrs. W. E. Cowan and Arthur Payne.

A set of slides by Mr. Bert Jackson, of Sunderland, was placed first, and a set by Mr. W. Coats, Junior, Tynemouth, second. The Council note with regret, that the judges recommend that the plaque be withheld, as the work entered in the competition is not of a sufficiently high standard to merit a Federation plaque, and hope that the work will be of a better quality in future competitions.

A loan collection of slides was got together from some of the leading slide makers in the north and circulated along with the competition slides, amongst the various societies who applied for same.

It is with regret that the Council received the resignations of Messrs. R. Borrow and H. L. Thomson, editor and business manager respectively of the "Federation Record," the publication of which is thereby suspended, and trust that a Year Book or other such publication will be established to take the place of the "Record."

The finances of the Federation are in a satisfactory condition.

The federated societies are:—Bishop Auckland, Blaydon, Consett and District, Crook and District, Dudley and District, Gateshead, Gateshead Teachers' N. H. Society, Hartlepool P. and S., Jarrow and District, Newcastle and Northern Counties, South Shields, Sunderland, and Tynemouth.

Blyth and District Camera Club has newly joined.

President (re-elected), W. S. Corder; secretary (re-elected), J. B. Scott, 2, Walton Avenue, North Shields.

## CINEMATOGRAPH BLINDNESS.

DR. EDWARD MAGENNIS writes from Dublin to a recent issue of "The Lancet" reporting a case which recently came under his notice demonstrating the effect which an intense white light, such as is necessary for a cinematograph exhibition, may have on the sensitive retina.

"A young lady, aged twenty-one years, consulted me with regard to what she called 'a sort of blindness.' The history was that up to the time she had witnessed a cinematograph display of about fifteen or twenty minutes' duration she had 'good vision and strong eyes,' but that when leaving the hall she experienced a difficulty in seeing objects and felt as if she were entering a darkened room. This continued for two or three hours and then, as adaptation of the retina gradually took place, objects became more distinct. She had considerable headache, a sensation of dazzling, and spasmodic contraction of the eyelids. These symptoms remained for about twenty-four hours. On the following day there was slight eye pain, with considerable reduction of the visual acuity. The pupils were of medium size and the reaction was normal. I advised her to remain in a darkened room, to have the eyes gently massaged, and to take a hot bath. I gave internally bromide of ammonium. She wore tinted glasses for some days and is now quite recovered.

"The condition produced by exposure to excessive light is some-

times spoken of as blindness of the retina, anæsthesia of the retina, and neurasthenic asthenopia. 'Retinal electrocution' is the term Darier uses when writing of the cerebral and retinal shocks produced by the passage of an electric current through the upper part of the body and the head. This suggests to me the term 'retinal cinematocution' for the condition produced by the intense flashes of white light. Those who have witnessed these living-picture displays must have experienced that peculiar 'tiredness' of the eyes caused by exhaustion of the retina, and how gratifying it was to close the eyelids and thus relieve the strain. Until some improvement takes place in the mode of exhibiting these pictures and in rendering less intense the light the public should be warned of the danger and advised to wear tinted glasses when looking at them, and each display should not exceed one minute."

## ON LIGHTING PROFILES.

(A communication to the Photographic Society of Philadelphia.) The mistake most amateurs make in photographing in profile is getting the illumination too flat, so that even a beautiful contour is marred in the making. A profile will be made most successfully by introducing the light rather behind the head, so as to throw the receding boundaries of the front of the forehead, eyes, cheek, nose, and chin into half tint. The principal light will be on the upper parts of the temple, cheek-bone and the ear; and the principal shadows under the hair, upon the cheek and temple, and under the eye-brow, close to the nose. The whole of the front of the iris of the eye will be light, except close under the eyelashes. The pupil of the eye will be scarcely visible, but the eye-ball will appear darkest where the pupil is supposed to be. With a light background, a beautiful relief will be given the head, especially if the background is kept at a considerable distance from the head, so as to secure atmospheric effect.

A profile illuminated as suggested above ought never to be underexposed, and care must be taken not to make the contrast of light and shade too violent; the object is to get delicate shadows by judicious use of reflected light rather than by employment of direct illumination. The reflectors should be of different shades, so as to modify the light.

One thing to remember especially in making a profile photograph is that the slightest difference in the angle at which the top or side light enters the studio and falls upon the head makes either a picture or an unmeaning blur. (We are not referring to artistic blur.) The photographer who desires this may secure it by racking a little out of focus.

We have said above that the most effective profile illuminations are generally those made by a side light behind the head, but it does not follow that all profiles should receive an illumination of this kind. Some features are more effectively illuminated by light more inclined to the front, but when a front light is employed a dark background must be used to secure proper relief to the head. The student may find some beautiful examples of effective profiles in the impressions of ancient Greek coins.

JOHN BARTLETT.

THE Right to be Photographed.—German gipsies at Haddington near Duns, are alive to the money value of their portraits. One photographer appearing in their camp he was immediately surrounded, and told he would not be allowed to take a snapshot without first paying 10s. They refused a shilling. The photographer paid the Parish Church gate between him and the band, but they came after him in force with a blanket held up in front, and when money was still refused, and the photographer attempted to take a snapshot commenced to throw mud at him.

THE Yorkshire Union.—The arrangements for the annual excursion to York, this year—are now completed and described in a circular issued by the secretary, Mr. Ezra Clough, 10, Farncliffe Road, Bradford. Special photographic facilities have been granted for the occasion.

ACCORDING to a daily paper, the Kaiser has had a Röntgen ray apparatus installed in the Castle of Prokelivitz, where he is now shooting, to determine the course of shots in large game killed on the royal estate, and to study the wounds caused by modern firearms.

## Exhibitions.

### KODAK PICTURES OF THE PRINCE'S TOUR.

An exhibition of over 150 photographs taken by the correspondent of the "Daily Mirror," Mr. Ivor Castle, who accompanied the Prince and Princess of Wales throughout their Indian tour is now being held at the Strand Gallery of the Kodak Company, near Charing Cross Station.

The collection includes an immense variety of subjects, from prior portraits under the most unfavourable conditions to snapshots in the blazing Indian light. The negatives, it is therefore interesting to state, were obtained in every case upon the Kodak film, exposed in one or other of the Kodak cameras. In their exhibited form the products of Mr. Ivor Castle's skill and tireless energy are presented as bromide enlargements by ringing the changes four of the five brands of Eastman bromide papers. The effects obtainable upon the "Royal," "platino-matt," and other Kodak bromide papers are sufficiently well known to require no description in us; enough to say that the exhibition permits the visitor to know how the papers have been turned to good effect in treating negatives of widely different character. The prints, we may also mention, represent only a portion of those taken in the course of the tour. The whole number would fill a gallery with many times the area of the wall space which the Kodak Company are able to set apart in their cool and comfortable retreat from the heat and noise of the Strand. The exhibition is open free to the public daily from 10 to 6, and on Saturdays from 10 to 2.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes.*

The following applications for patents were made between May and 19:—

**SQUEEGES.**—No. 11,224. Improvements in squeegees. John Wilkinson and Alfred Wilkinson, 4, St. Anne's Square, Manchester.

**BORDERS.**—No. 11,227. Improved means for printing borders on photographs. Robert White, 46, Appin Road, Dennistoun, Glasgow.

**CARBON TISSUE.**—No. 11,304. Improvements in the carbon process by enhancing the keeping properties of the tissue. August Schrieber, 37, Richmond Terrace, Clapham Road, London, S.W.

**COPIES.**—No. 11,312. Improvements in the production of copies of tracings, drawings, and other transparencies. Henry Lionel Shawcross, 15, Water Street, Liverpool.

**FILMS.**—No. 11,346. Improved photographic films for film packs, change boxes, cameras, etc. John Edward Thornton, Altrincham, Cheshire.

**PROJECTION.**—No. 11,416. Improvements in projecting photographs or transparent pictures in instantaneous succession on a screen by sunlight, and apparatus therefor. George Robson, Lloyd's Bank Buildings, Canute Road, Southampton.

**ENLARGING.**—No. 11,620. Improvements in photographic enlarging and reducing apparatus. Houghtons Limited, and James Wright Craig, Birkbeck Bank Chambers, Southampton Buildings, London.

**CINEMATOGRAPH FILMS.**—No. 11,762. Improvements in cinematograph films. Compagnie Generale de Phonographes, Cinematographes, et Appareils de Precision, 1, Queen Victoria Street, London, E.C.

### COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**ARTIFICIAL LIGHT.**—No. 3,128, 1906. The apparatus consists of a stand, carrying burners in tiers, usually three in number, the lowest one at a short distance from the floor, while the others are distributed to give an equal illumination over the whole person. Behind these burners is a large reflecting or diffusing screen,

which may be of light cloth carried on rails at the top of the stand, and varied in width by altering the angles of the rails or drawing in the screen. The burners are also adjustable in position to concentrate or scatter the light as required. A is the stand supported on the tripod legs *a* hinged to it, or carried in any other convenient manner. Gas is led to the tubular post through the pipe B, and upon the post are secured the two upper tiers of burners C and the lower tier C<sup>1</sup>. Three burners are shown on each side of the upper tiers and two on the lower, but

of course the number of burners and their arrangement may be altered. All the burners can be turned to any position required so as to distribute or concentrate the light in the most efficient manner. Behind the burners and carried by the stand is the reflecting screen D, consisting of a light curtain suspended on the arms *d* at the top of the stand, and hanging down to the floor. The arms *d* are pivoted at *d*<sup>1</sup> to the stand and are adjusted to give the required width to the screen, which may also be fully or only partially extended as found desirable. Owing to the distribution of the light, part of which comes

from the burners close to the floor, the sitter is illuminated from head to foot, and sharp shadows are eliminated by the reflecting screen which softens the light by diffusion. For taking the head and shoulders only the upper tiers of lights would be used, while for groups all the lights would be employed, spread out to their full width. Marwood Short, 1, The Collonade, Ramsgate.

**FOLDING CAMERAS.**—No. 10,600, 1905. The invention relates to a photographic camera having the rearmost part of the camera case—which has the bellows attached and carries the sensitive

surface—movable towards and away from the body of the camera; the combination of a certain construction to ensure movement of the rearmost part in parallel planes towards and away from the body of the camera, and a certain mechanism—adapted to be operated from the exterior of the camera case—for moving and ensuring the parallel movement of the rearmost part towards and away from the lens for the purpose of correctly focussing without movement of the lens with respect to the lens front. Arthur Lewis Adams, 26, Charing Cross Road, London, W.C.

A process for preparing pigment images in monochrome, polychrome, or natural colours, and printing plates, with a silver salt or an emulsion of the same. M. J. Mézaros. Fr. Pat. 352,815. March 30, 1905.

The present methods of preparing images in pigments and printing plates are based on the light-sensitiveness of bichromated gelatine. There are, however, some notable disadvantages. Thus, amongst others, it is not possible to make plates that will keep; Further, the sensitiveness is comparatively small, so that it is not possible to make photographs direct or enlargements on them, and one cannot follow the progress of printing. The new process obviates these disadvantages in that one can use the ordinary emulsions of bromide or chloride of silver; with these the original may be taken in the ordinary way, and the development, fixing, etc., is as usual. Great stress is laid on the importance of thoroughly washing after developing and fixing. The chromate necessary for the preparation of the pigment images is added afterwards to the gelatine, and is not used as a sensitiser. The silver image is immersed in a solution of bichromate of potash, or ammonia, or other salt for three or five minutes. It is necessary to fix in the film the chromic acid which has been absorbed by the gelatine in proportions corresponding to the shadows of the image. This is effected by immersing the plate in a solution which can dissolve the metal of the image, whilst at the same time the chromic acid precipitates the solution of the metal in the form of an insoluble chromate. For this purpose it is convenient to immerse the plate, after the chromate bath, in 2–3 per cent. solution of nitric acid. The chromate and nitric acid baths may be mixed. The insoluble chromate precipitated in the image-bearing film in proportion to the shadows, combines with the gelatine, so that the image may be developed with warm water in the usual manner of carbon printing, and only the soluble parts of the gelatine are dissolved. A gelatine relief is thus produced which may be hardened in the usual manner, and can be used for printing, or an electrotpe may be cast of it. The film of the image may be coloured with any convenient colouring matter to obtain a transparency—a negative for printing or a positive on paper, coloured at will; or a precipitate can be produced of any desired colour in the gelatine, for example, sulphate of baryta to make the image visible. When pigmentary or coloured images are required, the necessary pigments should be added to the gelatine before the coating of the plates, films, or papers. It should also be noted that besides the necessary pigments, orthochromatic sensitisers may be added, but these are quite independent and have nothing to do with one another. With the new process it will also be possible to obtain polychrome effects by superimposing several films with different colours, at the same time the different films may be orthochromatised so that each is sensitive to the colour contained in the film, or any other. It is thus possible to obtain colour effects of great diversity, and also in natural colours. It is also possible to produce in the same way images in the complementary colours to nature, and in the same way print in natural colours.

THE death took place on May 24, at his residence, High Street, West Cornforth, of Mr. John William Chambers, photographer.

SUDDEN Death of a Photographer.—The painfully sudden death took place last week of Mr. James Frederick Lowrie, of No. 1, Rectory Road, Beckenham, a photographer trading at Beckenham and Bromley in the name of "Valery." Mr. Lowrie dropped dead while taking a photograph of a girl in his studio at Victoria Chambers, High Street, Bromley. The deceased was fifty-three years of age. The cause of death was aortic valve disease of the heart.

## New Materials.

The Gem Tricol Plate (Revised Issue). Made by the Gem Dry Plate Company, Willesden Green, London, N.W.

The new issue of the panchromatic plate made by the Gem Company evidences the activity of this firm in matters orthochromatic. The aim of the company has been to provide a plate of moderate speed which is highly orthochromatic, which can be used as a red-sensation plate in three-colour work and at the same time may be applied to landscape orthochromatic work without a yellow screen. In this last connection the makers have had in view the production of a plate of such a character that the orthochromatic effect upon it when screened would be obtained in less time than upon a more rapid ortho-plate exposed through a filter. Without questioning the wisdom of such an objective, it is our belief that a plate requires more enhanced yellow sensitiveness to imitate the results of a screen plate. That the Gem plate possesses orthochromatic properties to a very pronounced order we have discovered in our experience with it, and the fact is clearly shown in tests which we publish below. But we nevertheless have found it difficult to suppose that a very decided gain was not obtained by the use of a yellow filter. As the makers say, the plate is not a rapid one; but for many purposes where speed is not the chief desideratum, but where colour-rendering is important, the new plates should be found altogether satisfactory.

The following are tests made by Mr. S. E. Sheppard, B.Sc., the sample supplied to us, Batch No. 4,642:—

Inertia (H and D pyro-soda). .42.

Blue sensitiveness . . . . .

Yellow sensitiveness . . . . . 4.5.

K (velocity constant of development with standard ferro-oxalate): .040.

$\gamma$  (density giving power): 3.12.

T (time for standard gradation of 1 with above developer). 9 minutes.

The light used in these tests is acetylene with the later screen (Phor. Journ., 1906, 46, 116), giving a closer approximation to daylight than the one used for the former tests (Phor. Journ. Nov., 1904, p. 292), but measured against the former so as to make the above comparable with previous figures given in these columns.

Wellington Self-toning Paper. Made by Wellington and Ward, Elstree, Herts.

This new introduction of Messrs. Wellington and Ward's reaches us with no indication of its character other than that it is a paper of the self-toning class. However, we were glad to see from the instructions that the fixing bath in which the prints are to be toned is to be kept alkaline by the addition of bicarbonate of soda in the proportion of 30 grains to the pint of bath. We first satisfied ourselves that this quantity is sufficient for the purpose. The bath as compounded in Messrs. Wellington and Ward's instructions is distinctly alkaline, and therefore the objection which is brought against self-toning papers prints on which are immersed directly in a plain solution of hypo—viz., that the toning action may be due to acid decomposition of the bath—cannot apply in this case. The makers direct that the prints be placed immediately in the hypo-bicarbonate, and while they cannot be criticised adversely for recommending this procedure, we were curious to see the effect of washing prints before fixing. The result of doing so, we found, was to increase to a very notable extent the speed of toning, or what amounts to nearly the same thing in the end, the coldness of the tone obtainable in a given time. We say nearly the same thing, because we obtained tones of a coldness on washed prints which we could not get on those unwashed, however long, within reason, we kept them in the hypo. The effect of the preliminary wash is so distinct and so beneficial to the manipulation of the paper that we referred the point to Messrs. Wellington and Ward, seeing that no mention of it was made in the printed instructions. They inform us that the same thing has been recently observed by themselves, and that the procedure is one which they recommend, and which they will advise in future instructions. The preliminary wash is scarcely any extra trouble, and the results are in every

an improvement on those without the wash. We say this with respect to the usual aim of users of self-toning papers at producing normal effects of separate gold toning. If the aim, however, is to produce prints of a very pleasing warm brown or sepia tone, then it is an advantage to omit the first washing in using Wellington P. We need say no more of the paper except that in depth and richness its results are admirable, and we congratulate the firm on having placed upon the market a material which yields results of perfection by a process which is theoretically and chemically perfect.

Mr. Sandell Films and Plates, Ltd., notify us that in future all their films will be issued colour-sensitive, the character of forthcoming batches being of a kind which is the result of recent improvements in manufacture.

## New Apparatus, &c.

"Primus" Film Squeegee. Sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

The drawing clearly illustrates the construction and use of this instrument. Lengths of roll film are drawn between the two

other blades, and so robbed of superfluous moisture. The handle which the rubbers are mounted is divided and hinged to facilitate insertion of the end of the band of film. The price is 2s.

**ARTISTIC LENSES.**—Some recent notes on the Eidoscope lens of Heris, Paris, sold in this country by Mr. F. C. Clarkson, Colchester, particulars of the optical properties of the lens submitted to which we have reason to believe have been misinterpreted by those who possibly have not read the articles on the qualities permissible or even desirable in lenses for the specific purposes of portraiture and other work in which an artistic effect is aimed at. It is therefore well for us to state the facts which are a natural bibliography of the figures and results we quoted. The Eidoscope lens, when stopped down, is capable of giving sharp definition over a moderately wide angle—that is to say, it may be used successfully in outdoor photography of various descriptions. At its larger apertures a certain amount of aberration is introduced into the image, and this introduction produces the very effect of slight diffusion which it has been the aim of Major Puyo and others to secure—for artistic effects in portraiture particularly. A number of prints in negatives made with the lenses which lie before us bear out the quality of the instruments—which, we learn, have been purchased to the number of more than twenty-five by one leading London firm of photographers, and are in use in several of the leading studios in the West End of London. These prints can be seen at our offices by any one calling within the next fourteen days, and the best method of judging of the lenses' capabilities, we may suggest, is to take advantage of the offer of the English representative to allow fourteen days' free trial of a selected instrument.

**NEGATIVES BY POST.**—The Tress Company, 205, Oxford Street, London, draw our attention to a new introduction of theirs for facilitating the safe transmission of negatives through the post. It consists of a stout case of tinned iron taking a plate box of quarter, half, or whole plate size. The box is pushed tightly into the case, the end of which is then closed and fastened by a simple catch.

The case has then only to be tied with string and a label attached to be ready for posting. The cases are strongly, though not heavily, made, and should withstand a very great deal of wear and tear. The prices are: whole-plate 2s., half-plate 1s. 3d., and quarter 1s., all post free. Reductions on these prices can be made when a quantity of the cases is despatched at one time.

## CATALOGUES AND TRADE NOTICES.

Messrs. Mawson and Swan have just issued a book of instruction for the use of their photographic products, in which they have assembled formulae for developers, hints on lantern slide making, and two chapters on orthochromatic photography. These latter provide some very useful reading at the present time when orthochromatic matters are so prominently before photographers, and we are glad to see that the author, Mr. Arthur Payne, has revised the matter and added a new section on "Orthochromatic Photography for Pictorial Effect." The book, which is obtainable free from Mosley Street, Newcastle-on-Tyne, contains a number of instructive half-

tone illustrations, among which is one of a photograph made with ordinary stage lighting with two seconds' exposure at  $f/6$  on a Mawson "Ortho B." plate. Another illustration of the effective use of ortho plates in landscape photography is reproduced herewith from a negative made on the "Ortho B." plate through an adjusted light-filter in one quarter-second exposure at  $f/6$ . We would advise our readers to apply for the publication, which Messrs. Mawson and Swan offer free.

A new booklet of "Ferrotypes Photography" has been published by Messrs. H. Dawson and Son, 42, Norfolk Street, London, W.C., and deals with the opportunities for profit in the rapid outfits, well known as the "Quta" and "Takukwick." These instruments for beach and bazaar photography have met with considerable success, and the hints on their manipulation contained in the little volume should therefore be welcome.

Messrs. Elliott and Sons advise us that on and after June 1 Barnet bromide and gaslight postcards will be put up in packets containing eighteen cards and two masks at the following reduced prices:—Ordinary size,  $5\frac{1}{2} \times 3\frac{1}{2}$ , 1s.; midget size,  $3\frac{1}{2} \times 2\frac{1}{2}$ , 8d.

A special list for professional photographers is newly issued by the Tress Co., 205, Oxford Street, London, W. In the matters of price and novelty the list contains much to attract custom from professional workers, for the firm issuing it has the reputation for swiftness in developing any idea likely to be of use to the profession, and its business is evidently run on a small margin of profit.

The price list for enlarged negatives, retouching, and other trade work, which reaches us from the firm of Zano, 4, Manor Road, Stoke Newington, London, N., discloses the very moderate charges made for work which is in frequent demand and which, we are pleased to find, is turned out of commendable quality. A print (before us) from an enlarged cabinet negative done in the ordinary way of business is excellent in preserving the character of the original.

The large new catalogue of the City Sale and Exchange reaches us from 91-94, Fleet Street, E.C., and contains, we find, very com-

plete descriptions of modern apparatus for amateur and professional. The "City Sale" is confident of its power to serve professionals, and an inspection of the pages of its list should certainly convince the buyer of the very inclusive character of its business facilities. The catalogue (300 pages) is offered free to B.J. readers.

By favour of Messrs. A. E. Staley we have been able to inspect a large series of prints from negatives of Canterbury Cathedral taken by Mr. Stanley E. Fincham, of West Dulwich. All the negatives, which number altogether about fifty, were made with one or other of the "Planastigmat" lenses, of which Messrs. Staley issue several varieties suitable for outdoor and studio photography. Canterbury Cathedral, by reason of its great height, is a severe test of the covering power of a lens, and therefore the prints before us, in which the field is covered sharply to the extreme corners in all but a few instances, constitute a remarkable testimony to the quality of the "Planastigmat" in this respect. We should add, also, for the information of those who have not photographed these particular subjects, that in many cases an extreme rise of front is necessary, and the work of the lens is therefore seen under the most exacting conditions. We are bound to admit that the prints demonstrate the ability of the lens to come through such an ordeal with great éclat. Previously we have reviewed in these columns certain of the series of the "Planastigmats," and we are therefore glad to have the opportunity of drawing attention again to the creditable work of these moderate priced instruments.

"THE PROFESSIONAL PHOTOGRAPHER."—Under this title a monthly magazine has appeared, under the auspices of Messrs. Kodak, Ltd., and will be issued at a yearly subscription of 6s. 6d. The first number, May, but issued a few days ago, is excellently produced, contains some pages of technical information on Kodak apparatus and products, and evinces the excellent policy of promoting good prices for good work.

FROM E. Merck, 16, Jewry Street, E.C., we have received the May issue of their very comprehensive list of chemicals.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
2 .....	South London Photo. Society...	Outing to Old Malden.
2 .....	Bristol Photographic Club .....	Outing to Bourton and District.
2 .....	Aberdeen Photographic Assn. ....	Outing to Bleidside and Corbie Linn.
2 .....	Scottish Photo. Federation .....	Outing to Loch Lomond.
4 .....	Everton Camera Club .....	Outing to Windermere.
4 .....	Worthing Camera Club .....	Outing to Midhurst, via Chichester.
4 .....	North Middlesex Photo. Soc. ....	Outing to Burnham and Paglesham.
5 .....	Hackney Photographic Society ..	"Question Box."
5 .....	Blackburn Camera Club .....	Annual Picnic to Chester and Eaton Hall.
5 .....	Southampton Camera Club .....	"Framing Photographs." Demonstration. Mr. T. L. Baker, Demonstration of "Platinochrom." Mr. S. G. Kimber.
6 .....	North Middlesex Photo. Soc. ....	Lantern Slide and Print Competitions.
6 .....	Edinburgh Photo. Society .....	Forty-Sixth Annual Meeting. Election of Office-Bearers and Councilors.
6 .....	Leeds Camera Club .....	Discussion on "Exposure."
7 .....	Hull Photographic Society .....	General Meeting.

NORTH MIDDLESEX SOCIETY.—Mr. J. McIntosh lectured on the 16th inst. on orthochromatic plates and filters. He pointed out that there is a doubtful advantage in using ortho plates without filters, and in nine-tenths of the work to be done a filter is absolutely necessary. And further, that the filter must be adjusted to the plate. Plates vary in regard to their sensitiveness to colours, some being adjusted mainly for yellow, others yellow and green, and the panchromatic down to the red. A careful test should be made with the filter employed upon a coloured diagram, as suggested by Sir Wm. Abney, to ascertain if it renders the colours in their correct value; and a further test should be made upon a chart with gradations of grey from very light to very dark, first without a filter, and then in varying increased times to ascertain how much more exposure is required. The two exposed plates to be developed together, and then it will easily be seen which gives the correct rendering to match the

plate taken without a screen. If a correct filter be used it will destroy atmospheric effects.

WALKLEY (SHEFFIELD) CONSERVATIVE CLUB CAMERA AND OPTICIAN SOCIETY.—At a meeting last week, a demonstration of bromide toning was given by Mr. H. S. Nutt, assisted by Mr. During the course of his remarks, Mr. Nutt particularly insisted upon his hearers that the platino-matt bromide of any make is most unsuitable for toning, this particular brand being made of black tones, as its name implies. No fewer than eleven different processes were demonstrated, four of them being (a) direct process, the remainder indirect, embracing, hypo-a-um, mercuric-platin, Ferguson's copper method; blue toning, which, by modification, gives green. The effect of bleaching with various agents, in the subsequent toning, was shown by successively bleaching on cupric bromide, cupric chloride, iodine, ferricyanide, and chloride of lime, followed by immersion of the bleached prints in a bath of sulphide 3 gr. to the oz., with one drop of hydrochloric acid added. Bichromate and Dr. Bradley's vanadium toning process were also shown.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At a recent meeting, A. R. F. Evershed gave a demonstration upon the oil-printing process. He claimed that the process could be either essentially automatic or essentially personal, and was as much under the control as gum bichromate. He considered "oil" superior to gum because it is a constructive process, whereas gum was destructive. The process is based on the fact that bichromated gelatine hardens on exposure to light, and that if it is exposed under the negative and afterwards soaked in water it absorbs moisture in inverse ratio to the light action. The moistened parts of such film would repel any greasy substance, while the hardened portions would retain it. The process has been fully explained in our pages, but Dr. Evershed claims to have discovered that thymol is the best preservative agent, and that those photographers who have attempted the process will find the following hints, which are the result of long experience, of great value:—

Much ink will be deposited if (1) the image is nearly dry; (2) the dabbing is heavy and slow; (3) the pigment is fine, and the brush well charged; (4) the temperature of the air is high.

Little ink will be deposited if (1) the image is very moist; (2) the dabbing is light and quick; (3) the pigment is stiff and the brush comparatively clean; (4) the temperature of the air is low.

NEW CAMERA CLUB.—A meeting of those interested in this matter was held at Charing Cross Hotel on the 24th inst. Amongst those present were Mr. Fraser Sandeman (in the chair), Rev. F. C. Lambert, Messrs. R. W. Craigie, A. C. Beard, Leonard Marshall, Leslie Clift, Child Bayley, Calder Marshall, Horsley Hinton, Holding, J. W. Jones, Duncannon, Pearson, E. E. Austen, J. G. Evans, Perrott Smith, Sanders, G. S. Russell, Powles, Cator, Simmelkjaer, Gurney, Cope, Scrivener, Fairholme, and Evershed. After a few remarks from the Chairman, pointing out how the closing of the old club had created a void in the photographic world, and how the absence of a club for purely photographic purposes was felt by a great many, he called on Mr. Fairholme, who laid before the meeting a scheme for the re-establishment of a camera club. He said the premises, now being rebuilt, close to Charing Cross, could be obtained at a reasonable rent, in which the following accommodation would be provided:—Club room, studio, enlarging room, four or five dark rooms, daylight room, and printing room. Light refreshments would be provided, but not luncheons or dinners. To work the club without loss would need 250 town members at 2 guineas annual subscription, and seventy-five country members at 1 guinea. Towards the membership he had received between seventy and eighty promises of support, amongst whom are the Duke of Newcastle, Viscount Maitland, Baron de Meyer, Colonel Paget, Messrs. Linley Sambourne, J. W. Gordon, Hebler, Farquhar, Laurence, Bale Rider, and many of those present at the meeting. To put the club on a satisfactory basis it was proposed to form a small syndicate with a capital of between £500 and £600, and towards this amount over £120 had been subscribed. Those joining the club would be required to take up one share in the syndicate. After a short discussion it was proposed by Mr. Evershed and seconded by Mr. Evans, "That it is desirable a camera club should be formed, and those present at this meeting pledge themselves to do all in their

er to promote this object," and carried unanimously. Several questions were then asked, and a discussion ensued in which the following participated: Messrs. Sandeman, Craigie, Clift, Beard, Hiley Hinton, Cator, Leonard Marshall, Gurney, Pearson, Evans, Fairholme, and Evershed, and it was proposed by Mr. Austen, seconded by Mr. Gurney, and passed unanimously, "That the following, Messrs. Craigie, Evans, Evershed, Fairholme, Pearson, Sandeman, and Perrott Smith, be appointed a provisional committee, with power to take all the necessary steps to form the club. At the suggestion of the chairman a guarantee fund for the preliminary expenses was initiated, and £30 subscribed. After a vote of thanks to the Chairman the meeting dissolved.

## Commercial & Legal Intelligence.

**BRISTOL Bankruptcy.**—A meeting of creditors has been held in connection with the affairs of Harold Edward Brightman, photographer, of 39, Colston Street. Mr. Frank Richardson appeared for the debtor. The statement of affairs shows liabilities amounting to £373, and the deficiency is explained at £333. The debtor attributes his failure to bad trade. He is thirty-four years of age, and as that he began business about seven and a half years ago in partnership with his father, who died in February, 1902. He also states that accounts made up at the time showed that there was a small surplus after providing for the liabilities, some of which the debtor subsequently discharged. The debtor's effects were disposed of for rent at the end of April, when the debtor instructed the auctioneers to dispose of the whole of his stock-in-trade by auction; and accordingly done, and the proceeds, after payment of rent and expenses, were paid to the debtor's solicitors. The sum of £19s. in their hands will be accounted to the Official Receiver. Household furniture is claimed by the debtor's wife, having been settled upon her prior to marriage in September, 1901.

**The Burton Bankruptcy Court** on Wednesday, Mrs. Eleanor Burton, a widow, lately carrying on business as a photographer at High Street, appeared for her public examination. The liabilities were stated to be £200 12s. 8d., of which £162 5s. 2d. was expected to rank, and, after deducting the assets (£58 15s.), there was a deficiency of £162 5s. 2d. Her husband's liabilities amounted to £308, but she thought his stock-in-trade would be worth £100, the debtor having the same instruments to work with when her husband died. She could not tell what she made in any year, although she repudiated the idea of the Official Receiver that it would be £500 a year. In trying to pay off her husband's debts she had failed to keep her head above water. The examination was closed.

### NEW COMPANIES.

**NORTHERN Photographic Company.**—Capital £7,000, in £1 shares. Require the business of a photographer, carried on at 18, Bank Street, Carlisle, by T. M. Laws. No initial public issue. First shareholders (not less than three nor more than seven): J. Dorman, Stocks, W. Carrick, A. McFarlane, and T. M. Laws. £10. As by company. 18, Bank Street, Carlisle, Cumberland.

**THEOBALD and Co.,** dealers in photographic goods, Staines, Middlesex, Hounslow.—A meeting of creditors was held on May 11, and a statement of affairs was submitted showing liabilities £1,657, assets £369. A composition of 6s. 3d. in the £1 was agreed to, payable 2s. 6d. down, 2s. 6d. in November, and 1s. 3d. in March, the first two payments being guaranteed by the debtor's mother and sister.

**ELLA-GRAY Photo Paper Company.**—£2,000, in £1 shares. Require the business, premises, and patent rights of the Photographic Development Syndicate, Ltd. (in liquidation), and to adopt an agreement with H. Jenkins. No initial public issue.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE PHOTOGRAPHIC CONVENTION.

To the Editors.

Gentlemen,—It has been suggested that, during the Convention week, one or two "straight talks" on business methods (after the American pattern) should take place among the professional photographers attending the meeting.

If those of your readers who think such a thing desirable will kindly communicate with me, I will endeavour to make the necessary arrangements.—Yours truly,

F. A. BRIDGE, Hon. Sec. and Treasurer.

East Lodge, Dalston Lane, London, N.E.

May 28, 1906.

[We hope the opportunity will be embraced.—Eds., B.J.P.]

### THE THEORY AND PRACTICE OF INTENSIFICATION.

To the Editors.

Gentlemen,—I am very interested in the bromide strips kindly made by Mr. E. J. Wall, toned with the uranium and ferricyanide bath. I am afraid, however, that they prove nothing, as in the cases where an absurdly disproportionate excess of ferricyanide has been used the colour of the print is greatly due to ferricyanide staining, whilst where a great excess of uranium has been used sufficient time has not been allowed for the colour to become what it certainly could have become—viz., redder. It is interesting to note that Mr. Wall's strips No. 5 and No. 6, which have been toned with just about the relative quantities of uranium and ferricyanide, that Otterberg states give brown and images respectively, are so similar in colour that the eye cannot tell any difference. Also, why is strip No. 8 distinctly browner than No. 7? This entirely contradicts all the other colour comparisons. Microscopic examination of the separated films indicates also that the brownest images are due to a little red deposit on the black silver image; the reddest images are due to much red deposit on the same black image. A quantitative examination of 2 sq. cms. of each of strips 1 and 9 showed that the film of No. 9 contained considerably over eight times as much unaltered ferricyanide of potassium as the film of No. 1. The coloration of No. 9 was therefore obviously due largely to yellowish-brown ferricyanide.

However, I do not see how the matter can be settled without definite molecular weight determinations, to see if an excess of uranium nitrate or ferricyanide induces two distinct compounds. My first experiments were conducted with the precise quantities stated by Otterberg, and my results proved that by giving the necessary time the negatives became the same colour within the limits of eye estimation; and, as a general rule, intensification made the gradation less steep with the excess of uranium.—Yours faithfully,

T. THORNE BAKER.

Cricklewood, N.W., May 28, 1906.

### TONING WITHOUT GOLD.

To the Editors.

Gentlemen,—In your reply to your correspondent, "Toning Without Gold," I am in perfect accord with your remarks in reference to the addition of acids or any other substance to the fixing bath that will decompose it; such methods are indeed "vile."

But I do take exception to the earlier remark "that the advantages of any method of doing without gold are illusory," providing you refer to sound methods of development; and I call any developing formula containing an appreciable amount of acid in it unsound, as most of the published formulæ are; but I do say that a developed image depending on the toning action of pyrogallol and metol for its tone, apart from acid, is the equal in every way (never mind

about being superior) to gold. Both these chemicals possess a strong toning action, in contradistinction to hydroquinone, prints developed with which must be subsequently gold-toned.

I am sending you three developed prints on P.O.P. (matt, glossy, and a postcard) developed with the above agents, fixed in pure hypo only, and which are as permanent as any silver print can be.

I consider the pure sepia tones vastly superior to the purplish tones of gold, whilst there is no comparison regarding the relative simplicity of the methods.—Yours faithfully, H. J. MALLABAR.

59, Deane Road, Liverpool,

May 25, 1906.

#### To the Editors.

Gentlemen,—In your reply in paper of this date to postcard as to "Toning Without Gold," you characterised the acid fixing as a "vile method," which, in your opinion, it may be. But you say it is "not permanent." All I can say I have a print done and toned so fifteen years ago, which shows no change. It is framed and exposed to light.

1. I wash prints thoroughly.

2. I harden, etc., by using Ilford method: alum, salt, water. Wash well.

3. I fix in hypo, 3 oz. to 20 oz. of water, a drop (not more) of G.A. acid to each oz. of fixing, for ten minutes. Wash well. I get a reddish-brownish tone, which I find many like well. I find it as permanent as any method.

J. L. LYELL.

30, Christchurch Road, S.W.

[Our comments were obviously made in reference to toning not to development. Our first correspondent might have assumed our attitude towards development of P.O.P. from the fact that we have published a number of articles on the subject of late in the JOURNAL, and devote some pages of the current "Almanac" to the same process. Of the prints sent, two are a warm brown and the other a purplish brown. All are free from stains and markings on the backs.—Eds., B.J.P.]

#### THE STATE OF WINCHESTER CATHEDRAL.

##### To the Editors.

Gentlemen,—Your correspondent in the last issue of the B.J. is strictly accurate in his statements re the restoration work at Winchester Cathedral. But in case his laboured account should be taken more seriously than is warranted, let me say that the Conventioneers need not have the slightest fear of not being able to find abundant photographic work at Winchester Cathedral, as certainly only one-sixth of the building, either exterior or interior (and that not the best portions from a photographic point of view) is unavailable for photography, and in my opinion there is a far larger superabundance of splendid work available than can be done in the few hours at the Convention's disposal on the day they are to visit Winchester.—Yours faithfully,

S. G. KIMBER,

Local Hon. Sec., P.C.U.K.

Southampton, May 28, 1906.

#### PROFESSIONAL COLOUR-PHOTOGRAPHY.

##### To the Editors.

Gentlemen,—I thank you for allowing Captain Davidson unconsciously to corroborate my statement that in 1903 I started colour photography at my studio. Looking over my notes, I see that I took Dr. Jumeaux's first portrait negatives June 10, 1903, and I presented him with the same. Six days later Captain Davidson called for the first time for the same purpose, and he accepted the same favour. It was not necessary for him in fraternising ways to say he called frequently, without adding that I paid for all the three-exposure sittings with the negative sets.

This belongs really to my technical training, for which I paid the piper with Lumière's filters, plates, material, instruction, etc., and to question me as to what I received from customers is uncalled for.

I am sorry I cannot give a technically instructive reply, so please excuse me for omitting personal references from this condensed form of defence, but the fact remains that for three months, from August 1, 1903, I showed specimens in my show-window, and

I was perfectly ready to accept and execute orders for colour photography.—Yours respectfully,

OTTO PFENNINGER.

Gentlemen,—As doubtless Captain Davidson would regret publication of inaccurate statements, and in justice to Mr. Pfenniger whose efforts in the direction of portraiture in colour seem unhappily to have been premature, I will call to your notice the fact that Mr. Pfenniger, of Brighton, and Messrs. Heath and Stoner of Plymouth, had, previously to the date mentioned, viz., 1903, experimented largely in the direction of portraiture by tricolour methods then available.

One thing is quite certain, and that is that Mr. Pfenniger using Lumière plates and filters from October, 1902, and that I in my possession a set of three-colour negatives of myself taken by Mr. Pfenniger early in 1903, at which time Mr. Pfenniger showed me tri-colour results which were certainly exhibited in his reception room as samples of his work, and, as far as my knowledge goes, first to be exhibited commercially.

Personally, I am sorry to see that the pursuit of what is doubtfully destined to be the leading feature of the near photographic future should show petty jealousies which can only draw the attention of those concerned from the object in view.—I am, Sirs, yours faithfully,

THOS. K. GRANT.

4, Bloomsbury Street,

New Oxford Street, London, W.C.,

May 26, 1906.

Gentlemen,—I notice in the BRITISH JOURNAL OF PHOTOGRAPHY May 25 the letter of Captain Lascelles Davidson, in which he is quite accurate, leading one to suppose that Mr. Pfenniger does not use his studio for portraiture in colours as a business, but only for experiment. He was taking portraits in colour when I first called on him, early in June, 1903, and he showed me some of his work. He afterwards let me have two sets of negatives (portraits of ladies) for me to get some results by my process for comparison with the one he was using.

Very soon after, I introduced Captain Davidson to him, who has several sets of negatives taken of himself in uniform.

I really think it is due to Mr. Pfenniger that he should have the credit of having opened a studio for portraiture in natural colour in 1903.

Portraits of two ladies and myself in colours, by my process from his negatives, were among those of mine which were exhibited lately at the offices of the BRITISH JOURNAL. These were taken in June or July, 1903.—I am, yours faithfully, B. JUMEAUX.

Southwick, Brighton, May 28, 1906.

[Having allowed both sides to express their views, we must decline to permit our space to be used further for prolonging the discussion.—Eds., B.J.P.]

#### SULPHITES AND THE PYRO DEVELOPER.

##### To the Editors.

Gentlemen,—Like your correspondent, Mr. Parlow, I also tried Mr. T. Thorne Baker's developer, and found it not only much inferior to metol-quinol, but also less satisfactory than a normal pyro-soda developer.

As I did not wish to make up 50 oz. of each solution I calculated out the quantities per ounce of mixed developer, and the following is the result taken from my notebook:—

Pyro .....	4.375 grains.
Sulphite .....	21.775 "
Soda Carb. ....	54.687 "
Citric acid .....	4.375 "

Now, as the two latter must combine, I have calculated out the result, and as much as 9 grains of carbonate (or perhaps less) would be neutralised, and  $7\frac{1}{2}$  grains of sodium citrate be formed. Even then there are 45 grains of carbonate in an ounce; surely this is quite unnecessary, as the average quantity recommended by plate makers is 24 grains. If the extra quantity is used to neutralise the effect of the citrate restrainer, would it not be more reasonable to omit the latter and reduce the soda, and thus make a saving in the cost, and get a workable developer?—Yours faithfully,

London, E.C.

A. GASCOIGNE.

# METRIC MEASURES.

To the Editors.

lemen,—Surely the "Ex Cathedra" note at the bottom of ening page of your issue of to-day must have been written with- efficient consideration. Has it ever been proposed to abolish e of vulgar fractions in any reasonable man's advocacy of tric system—far less that of halves and quarters? Of course, ay be fanatics who have said things which may be construed n this, but such do not represent the generality of advocates. ould be quite open for anyone to use, if he chooses,  $\frac{1}{2}$ ,  $\frac{1}{3}$ ,  $\frac{1}{4}$ ,  $\frac{1}{13}$ , or any other fraction of an unit which he may like, pro- only that when he proceeds to measure out such quantities in e he makes use of the weights or measures legally sanctioned at is pretty much the practice now.

s quite true, as you remark, that there are units of weight easure in the definitions of the metric system which are rarely and which have therefore become to a great extent obsolete; it an objection to a dictionary that it has too many words in ny of which are not in general use? They are available er required—as, in fact, some of these are—and a rich vocabu- usually considered as a recommendation to a language.

say there is no equivalent for the ordinary pound or chain. he half-kilo. is used in France instead of the old livre, and many for the pound. It is called by this name, but this e is not illegal any more than in England it is illegal to of a shilling as a bob.

next proceed to say that there is no chain. Assuming that ean a survey chain of 66 ft., I would call your attention to ct that the legalised chain for this purpose in France is the e decametre (65.81 ft.), which is as convenient a length in use. ain only derives its convenience from its relation to the acre ile; with them, it would go, but it is quite possible to replace

for dozens and grosses, as there are several of each as terms le, they might well make room for definite words, but no ones e, to make the use of the words illegal; only if disputes arise atter must be expressed in sanctioned units. There will then oublets arising from customs of trade, whether local or general. ry man knows exactly what a pound or a shilling is (money), less he is acquainted with the customs of trade he requires erpreter to make his bargain, and this is a hindrance to the ansaction of business.

re are two parties to a bargain. The buyer is obliged to pay l tender, and his side of it is quite definite; the seller takes age of customs, and may employ terms which in English mean ing quite different from that in which they are used, in fact, ight as well speak in a different language.

effort was made long ago to remedy this by the Imperial ts and Measures Act, but it has failed for reasons which need e discussed here. It remains to be seen whether the introduc- e the metric system will avail.

ourse, that system will not meet everyone's convenience and e perfectly, and it cannot but cause some trouble and inconve- at first; but it is approved wherever it is in use, that is, e civilised nations except British-born ones.

sting that you will pardon the length of this letter, I am, en, yours faithfully, J. F. TENNANT, Lieut.-Gen., R.E. Clifton Gardens, Maida Hill, W.,

May 23, 1906.

note was written in condemnation of the metric system, y drew attention to the remarkable report of the Postal Con- and to what appeared to be most probable reasons for the e being opposed by the representatives of metric countries. e regard to the chain, this unit, we believe, was originally d, and the double decametre (which has been supplemented econd chain of 25 metres) was only legalised in acknowlegd- e the fact that such a special unit was found to be necessary. as the whole point of our note. Units not forming part of mple decimal series have proved to be necessary, and con- exists owing to the retention of old convenient units, and euction of new ones. From sundry sources we have been led erstand that in several metric countries the confusion that n regard to weights and measures is as bad if not worse n this country.—Ebs., B.J.P.]

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, includ- ing queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\*.\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

A. G. Silvester, Church Square, West Hartlepool, Durham. Photograph of Sir Thomas Richardson.

E. W. Wiggell, 38, Alexandra Place, Sirhowy, Tredegar, Mon. Photograph entitled "Coming to Market in South Wales."

W. Sheeran, Watercastle, Duvrow, Queen's County, Ireland. Two Photographs of a Dinner given by Viscount De Vesci to his Workmen on his Estate at Abteyville.

J. G. Ewell, Oldtown, Abbeyleix, Queen's County. Two Photographs of Lord and Lady De Vesci.

R. Brown, Boulevard, Weston-super-Mare. Photograph of Christ Church Old Boys Football Club.

HUBL's "THREE-COLOUR PHOTOGRAPHY."—Could you kindly tell me the publisher of Von Hübl's book, translation by Klein, and the price for the same, stating whether it is nett or otherwise?—M. R. RONALD.

Penrose and Co., 109, Farringdon Road, London, E.C. Price 7s. 6d. published.

STUDIO BUILDING.—As I am about to build a studio I would like you to give me a little of your valued information. Is 10ft. wide enough? Is the glass side high enough at 8ft. for background? Is it good to block out the light at 3ft. from both ends, and do you think, generally, would you get a good light in it? It will have N light. Cheapness, together with good workmanship, is my chief object. Would I be able to take midget three-quarter length in this 27ft. By answering above you will much oblige.—"SPECULATE."

Ten feet wide will do, but a foot or two more would be better. With this length of studio 5ft. or 5ft. 6in. at either end might be opaque with advantage. It would be better if the ridge were carried higher than is shown in the sketch, if the garden wall will allow of it. With regard to the quality of work that can be done in the studio it should be excellent. Three-quarter midget pictures can be taken, unless the lens used is of extra long focus. The sketch has been returned as desired.

FERROTYPE PLATES.—(1) Can you tell me, through the medium of your paper, a way to keep thin ferrotype plates from denting? (2) Also a good preparation for cleaning same?—V. B.

(1) The only way we know of keeping them free from dents is to handle them with ordinary care. (2) There are many ways of cleaning the plates. Common whiting and methylated spirit is a very simple way. Rub it over and let the mixture dry on the plate, then polish off with a clean leather.

OWNERSHIP OF NEGATIVES.—Over a year ago I was asked by a client to take a number of views and to supply him with a print of each for the purpose of reproducing postcards. Including travel- ling expenses the amount came to £4 4s., which I had a little trouble in getting paid. He now threatens to take proceedings against me if I do not give him the negatives. Nothing was ever said about negatives. Are the negatives his property or mine?—N. B.

Let him threaten; the negatives are yours. It has been decided over and over again in County Courts, and also in the High Courts, that the negatives are the property of the photo- grapher, and not the customer. A number of cases are cited on page 738 of our volume for 1899; also a case in the High Courts,

on page 250 of the volume for 1903. See also the Almanac for the current year. You must bear in mind that although the negatives are your property, you must not use them for any purposes of your own.

**PLATINUM PRINTING.**—Can you give me in next issue of B.J. any information, or mention any works published on the manufacture of platinum paper?—**PLATINO.**

"Platinotype, Its Preparation and Manipulation," by Sir Wm. Abner and Lyonel Clark. 2s. 6d. "Photographic Reproduction Processes," by P. C. Duchochois. 2s. 6d.

**CLEANING PAINTING.**—Will you kindly, through your paper, tell me how best to clean a painting (oils)? Also could you give me the Photochrome Co's. address, as I cannot find it in the JOURNAL?—**F. R.**

If the painting is a valuable one we would advise that the work be put into the hands of a professional picture cleaner and restorer. If not, and it is only dirty, try the following:—First wash the picture with a sponge and lukewarm water, and wipe dry. Then cut a potato in half and rub over the surface with that—using a circular motion. After this go over the picture with the sponge and water again. If you desire further information we must refer you to the "Carvers' and Gilders' Guide." It may be had, if still in print, at Kent and Co's, the publishers. The address of the Photochrome Company is 35, Hosier Lane, Snow Hill, E.C.

**P. E. M. (Hford).**—We know of no such list.

**SUNDAY PHOTOGRAPHY.**—The superintendent of police in this division sent a sergeant down to my shop to tell me if I was caught taking photographs in my studio on a Sunday he would report the case, and that I was liable to prosecution. I write to ask you if he can do so, and under what Act of Parliament the summons will be issued? He said it was Sunday trading, and not a work of necessity. Do you consider it Sunday trading? I do not open the studio as a general thing on a Sunday, but I just go up to the place by appointment and take those who cannot get to the studio on any other day. I accept no money in payment for them on that day. I had no idea that photographers were liable at all, as I do not sell anything on that day. If I am liable in — I ask why are not others liable in towns of this Universe? What is the meaning of this particular case? I have taken photographs on Sunday, and so have my predecessors, and I am at a loss to know why I have been so suddenly stopped. I enclose two cuttings taken from the B.J.P. for this week, which shows that Sunday duty is quite common.—**S. K.**

The Act of Parliament under which proceedings will be taken, if they are taken, is the antiquated one passed during the reign of Charles II., which has never been repealed. While it is still on the Statute Book it can, of course, be put into force. This is rarely done nowadays, and when it is it is usually by local "powers that be" who are of the ultra "goody-goody" type. Photography, as a business, is largely carried on all over the country on Sundays, but it is seldom that any one is proceeded against, though, of course, all are liable to prosecution for carrying on their trade on the Sabbath, whatever it may be, with but a few exceptions. The fine, however, is limited to five shillings. You say you take no money on Sundays; that makes no difference. You are following your worldly calling. Under this same Act you cannot recover money for any work you may do on the Sunday.

**STUDIO LIGHT.**—Would you be so good as to advise us in the following studio query? The studio is 30ft. x 12ft., 14ft. to ridge and 7ft. 5in. to eaves. As originally built all glass was plain clear, the upright position being somewhat close to a shrubbery. The slant not having quite a clear sky space, the interruption being a very high red-brick side of house about 30ft. away. We have recently secured upright glass (ground glass effect) and improved lighting. The question we wish to know is whether obscuring the roof light in a similar way would improve the lighting further, or reduce the light too much? (We are inclined to think that ground glass does not make a studio slower). The trouble with all clear glass is a very hard and uneven shadow on dark side of face.—**CLARENCE.**

Ground glass, if kept clean, does not make the light materially

slower, and it certainly tends, with some aspects of the studio to give softer shadows by diffusing the light more than of glass. We should advise you to try treating the roof glass in the same way as you have done the side. This you may do temporarily by covering it with white tissue paper. You will see if it is an improvement or not.

**BLOCKING MEDIUM, ETC.**—1. I shall be glad to know if you have a formula which you can give us in your next issue for preparation of a paint of pigment for blocking out negatives. We use a large quantity, and require one that will dry quickly. 2. Also, we shall be taking at an early date a number of negatives at a motor meeting, necessarily giving very short exposures possibly so small as 1-1,000th of a second. In all probability some of these will tend towards under exposure, though we are using a focal-plane camera. Will you therefore be so kind to recommend a developer which will give bright results?—**A.**

1. As a blocking-out mixture for machinery, etc., in negative there is nothing better than the best Indian ink ground in china dish as a draughtsman prepares it for his drawing pen. For blocking out larger areas a quick-drying Brunswick black is very suitable, and so are the mixtures sold commercially for the same purpose. 2. Pyro-metol is as good a developer as for the purpose:—A: Pyro 80 gr., metol 70 gr., potass. metol sulphite 180 gr., potass. bromide 30 gr., water 22 oz. B: Sodium carbonate 3 oz., water to 20 oz. For normal exposures increase the proportion of B and add water.

**R. R. R.**—You would be able to obtain what you want from F. and Co., Fulwood's Rents, High Holborn, or possibly from Lumière N.A. Company, 4, Bloomsbury Street, E.C.

**GOLD CHLORIDE.**—I have an old 9 carat gold chain that is very much worn. Could I easily convert it into gold chloride solution for my own use?—**TONING.**

If the chain is immersed in nitric acid 1 part, hydrochloric acid 3 parts, and heated by means of a water bath it will gradually dissolve. Then you would have to precipitate the alloyed metals. You would find it much easier and quite economical to send the chain up to one of the refiners, who would send you its value in gold chloride.

**W. W. R.**—A neutral grey is about the most suitable colour. I should not recommend you to put in a dark room larger than, say, 4 ft. square, i.e., sufficient for changing plates and developing one or two exposures at a time. It might be placed in either corner at the back of studio.

**THREE-COLOUR PORTRAITURE.**—1. Some time ago you were recommending professionals to make use of specimens of the tri-colour photography as a new means of attraction. I have mislaid the article, and ask that you will either give me the address of the firm through your correspondence column or send along another copy of the JOURNAL of that date to me.—**F. R. W.**

1. The Rotary Photographic Company, Ltd., 12, New Union Street, Moorfields, London, E.C. 2. The "Almanac" is obtainable now with difficulty. Better write to a large dealer, such as Houghton's or Butcher. We have none. 3. Other three-colour firms are: Sanger, Shepherd, and Co., Gray's Inn Passage, London, W.C.; Fuerst Bros., Philpot Lane, E.C.; and The Autotype Company, New Oxford Street, London, W.C.; and the Lumière N.A. Co., Bloomsbury Street, W.C.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The Photographic Convention.—The full programme for the Southampton meeting is given on page 443.

The Paris Salon which was to have opened to-morrow has had to be postponed for a few days. It will open to-day week, June 15. (P. 445.)

Proposed improvements in London streets threaten the present use of the Royal Photographic Society in Russell Square. (P. 441.)

Protest is being made against the recent new arrangements for photographing objects in the British Museum. (P. 443.)

The value of a colour chart in ascertaining the properties of rhochromatic sensitisers in the copying of coloured objects is the conclusion of Baron von Hübl from a series of comparative experiments with the spectrum and a colour chart. (P. 446.)

The one-plate one-exposure colour method of Powrie is among the patents of the week. (P. 454.)

A modification of the method of making replicas of diffraction gratings has been published by Mr. R. J. Wallace. The advantage of the new method is that the replica dries without further shrinkage once it has been mounted. (P. 450.)

In the course of some notes on photographic varnishes, attention is drawn to the excellent celluloid varnishes sold as "cold lacquers." (P. 445.)

A review of photo-engraving methods by Mr. N. S. Amstutz is reprinted on page 451 in continuation of the recent paper by the same writer on the relief of half-tone blocks.

A new self-development paper containing gallic acid and free silver has been patented by the Lumière brothers. (P. 450.)

A recent work by the Hon. John Collier, "The Art of Portrait Painting," contains a number of lessons for photographic portraitists. A review of the book, by Mr. F. C. Tilney, appears on page 444.

The photographic portraits by Dührkoop are being shown in important provincial centres during the next twelve months. (P. 457.)

## EX CATHEDRA.

### Superb Technical Photography.

Yesterday there opened at our offices a small exhibition of photographs of flowers and animals by Mr. Henry Stevens, better known, perhaps, for his photography of these subjects ten years ago than he is to-day, when many possibly who are familiar with the auction rooms of "J. C. Stevens," King Street, Covent Garden, do not recognise in the present head of the firm the amateur photographer who has carried off a number of awards at past R.P.S. exhibitions at Pall Mall, and has received many other medals and prizes for his photographs of flowers and domestic pets. His renderings of subjects of such opposite character and of such opposite requirements in photography as a group of foxgloves and a couple of terriers show a mastery of technique which has probably never been equalled. Technical perfection, as that term used to be understood in photography, is rarely to be seen in these days of impressionism. The exhibitions offer no outlet for it. The R.P.S. which medalled Mr. Stevens's work three times in the old Pall Mall days would very likely place it among the refusés from the New Gallery, or accord it the debatable solace of space in the technical section. For this reason we have been fortunate in persuading Mr. Stevens to arrange a collection which does justice to his continuous work and is an education in what can be accomplished by the photographic process in the rendering of subjects which amateurs delight, and professionals are often called upon, to photograph. We shall refer further to the photographs next week, when we shall present an art supplement of one of the flower studies.

\* \* \*

### The R.P.S. House Threatened.

It may be remembered that the recent report of the London Traffic Commission advocated the construction of a new main road from Victoria Station to Whitechapel. This East and West thoroughfare was to be intersected by a widened Gray's Inn Road, which would be continued in a southerly direction across the river down to the Borough. The East and West road in this scheme would cut through the centre of Russell Square, and probably just miss the premises of the Royal Photographic Society, which are on the eastern side. The scheme is not altogether a satisfactory one, particularly as regards the North and South avenue, and an amended edition has now been suggested by Mr. Paul Waterhouse. (See "Architectural Journal," May 26, 1906.) This is distinctly superior, as the new North and South route is taken on the line of Kingsway and Southampton Row, but a point of interest to members of the R.P.S. is that it involves the destruction of the whole of the east side of Russell Square and the abolition of the present R.P.S. premises. At present it is only a

scheme, but of the two proposed it is so evidently the better that it will probably have the preference if the contemplated improvement is carried out at all. Possibly this compulsory move might be advantageous rather than otherwise to the R.P.S., and though the prospect is not imminent, it may be as well to bear in mind the fact that it is not altogether improbable.

\* \* \*

#### Visitation Day at Royal Observatory.

This annual event, which is much looked forward to by many interested in science, took place on Wednesday, May 30, and the visitors present included several members of the Royal Photographic Society. There is, perhaps, not very much to be seen of interest to the ordinary photographer, though the photographic work of the Observatory is carried out on a fairly imposing scale. From the report, it appears that no less than 12,000 prints were made during the year, while something like a thousand negatives were secured. This is not a bad record of photographic work, though, as a matter of fact, the number of negatives taken is less than in previous years, when the great photographic chart of the stars was in its early stages. It is to be noticed that the Observatory is still contemplating additional buildings. Since we first visited it, in 1893, the progress made in erecting new buildings and providing new instruments has been truly remarkable. The old Observatory can have never before witnessed such a busy thirteen years.

\* \* \*

#### A Menace to the Observatory.

From his annual report to the Board of Visitors to Greenwich Observatory, last week, we see that the Astronomer Royal complained that the continued efficiency of the Observatory is seriously threatened by the schemes for the supply of electric power for the whole of London and surrounding districts from generating stations situated in the immediate vicinity of the Observatory. Amongst these, he says, the chief and most serious danger arises from the generating station of the London County Council, which is planted exactly in the Greenwich meridian, in a position where its excessively tall chimneys will interfere with the observations of the stars near the northern horizon, and will render the results of observations untrustworthy on account of smoke and currents of heated air. He adds further that, as this generating station stands at a distance of only half a mile from the Observatory, there is grave risk that the vibration from the extremely powerful engines installed there for the supply of electro-motive power for the tramways and other works, will seriously affect the value of observation by reflections from the mercury horizon which are essential to the fundamental work of the Observatory. It would be a serious matter if the extremely delicate work carried on at the Greenwich Observatory were materially interfered with by the London County Council's generating station. But that body, we fear, has little consideration for such places as Royal Observatories. The curious thing is that the Greenwich authorities should not have anticipated the effects of the electric station before it was erected.

\* \* \*

#### Photography at the Madrid Outrage.

It appears, according to Reuter's special service, that some one succeeded in securing a snap-shot of the late dastardly attempt on the lives of the King and Queen of Spain at the moment of the explosion of the bomb, and that a reproduction of it had appeared in one of the Spanish illustrated journals. The account goes on to say that the picture shows a dense fog of dust, from the middle of which emerge

the figures of three mounted soldiers, one apparently headless and another with his arm upraised. In front of the carriage one horse is lying dead, and the other seven are spread across the street in a panic. One is oftentimes apt to discount largely anything relating to photography which appears in the daily press, but there is nothing improbable in the assumption that a very successful snap-shot was actually taken at the exact moment the bomb exploded, seeing that photographs were being snapped continually during the procession all along the route. Quite by accident, this one might have been obtained at the precise moment of the explosion. The negative should be of great value to its owner, whoever he may be, but, possibly, the publication of prints from it may be prohibited.

\* \* \*

**The Size of Enlargements.** We were recently reminded of the need which at times exists of advising a customer as to the size of an enlargement by seeing, in a new restaurant recently opened in London, a photographic enlarged portrait of the proprietor hanging on one of the walls, presumably for the purpose of attracting the attention of visitors. Yet the portrait, a 12 by 10, appeared utterly insignificant in its position on a panel of considerable size, and, at the distance at which the stream of outgoing persons passed it, could not be recognised for anybody in particular. A print at least 30 by 20 was needed for such a position, and, no doubt, had the management had their attention drawn to the fact when the enlargement was supplied, they would have been glad to have ordered one of the larger size. We mention the matter as a reminder of the occasions when the photographer will not be out of place in questioning his client to the end the work which he is about to execute will be satisfactory in every respect.

\* \* \*

#### Sunday Photography.

Sunday photography, as a business, is now being practised to a great extent throughout the country as well as in the metropolis. Many who follow it may not be aware that they are doing anything that is illegal. Nevertheless, it is illegal for anyone to carry on his business on the Sabbath. Last week we answered a correspondent who had been warned by the police authorities that he would be proceeded against if he continued to take photographs on Sunday. The writer, like many others, was unaware that he was infringing the law by what he was doing, and asked under what Act of Parliament he can be prevented from plying his trade. The only Act under which proceedings can be taken is the practically obsolete one passed in the reign of Charles II. It is still on the Statute Book, but is very rarely put into force. If it were there would be no Sunday trade carried on at all, either in photography or anything else. The Act permits meat to be sold in public-houses, and milk and mackerel between certain hours of the day. Neither by this Act is anyone allowed to work on the Sabbath, except works of necessity or charity. We allude to this portion of this Act to show the absurdity of it at the present day. However, it is only in country places—where the ruling spirits, the local magistrates, "the great unpaid," are of the strict Sabbatarian type—that the Act is put into force. In one small town the same tradesman has been fined between two and three hundred times for carrying on his business on the Sabbath. He still goes on, undeterred, in his Sunday business. The utmost fine that the magistrates can inflict is five shillings, whether the offence is the first or the hundredth, and in most instances the trade done will leave a fair margin of profit on the day's work after the payment of this sum.

**day ing.** If one looks through our advertisement columns, "Situations Vacant," one sees commonly that "Sunday work" is stipulated for, and is quite sufficient to show the extent to which Sunday photography, as a business, is followed without let or hindrance. We have heard that in some places more business is done on the Sunday than on all the other days of the week put together, and this is not altogether surprising. It is considered that many want their portraits taken on their "Sunday best" clothes, and to don them on a day would often, with the working classes, mean the end of a day's work. Notwithstanding this, photography is not to be classed as a work of necessity, neither can it be a work of charity. Therefore everyone who practises it as a business on the Sabbath is liable, under the antiquated law of prosecution and being mulct in a fine of five pounds. Lord Avebury's efforts to obtain legislation on any closing must be considered in connection with the fact, though it is improbable that the present Parliament will forward any Bill on the question.

**ography** Until recently reasonable facilities have been afforded by the authorities for photographing books, MSS., prints, and other objects in the British Museum without payment of any fee, but in February last new regulations came into force which are meeting with considerable disapprobation on the part of those who have gone on to make photographs or who employ others to do so. Under the new arrangements a fee is payable according to the following scale:—For one negative, two pence (if the exposure should exceed an hour, the fee is a time fee). For more than one negative the fee is a time fee—viz., two shillings for the first hour or part thereof, and one shilling for each succeeding hour or part thereof, in the day. The time spent in preliminary adjustment of apparatus and in clearing away to be charged. Beyond these fees, the authorities may also demand copies of each photograph taken, so that in some cases might happen that the expense of complying with the regulations was prohibitive. There has appeared in the "Times" and elsewhere some correspondence on the subject. Naturally, the imposition of a fee at all rouses some objection, but, granting its necessity, the system of charges does not appear to be an ideally equitable one. As the Museum is a public institution, and as the dissemination of photographs of its contents directly assists the object for which it exists, the restriction on photography should be no more stringent than absolutely necessary.

## OUT PHOTOGRAPHIC VARNISHES AND VARNISHING.

For persons, we imagine, when they have had a valuable negative injured or, perhaps, irretrievably ruined through contact with damp printing paper or, possibly, from the negative having inadvertently been left out in rain, have regretted that it had not been varnished in the first place. Yet such an incident, in many cases, does not prevent them from protecting their negatives in future by making a rule to give them a coating of some protecting varnish. In the days of the collodion process, varnishing was absolutely necessary, as it was next to an impossibility to get even a single print from the negative without ruin, if not ruin, to it, so delicate was the film. With the modern negatives, however, the film is so hard that there is little fear of its suffering from mechanical injury; it is only moisture only that is likely to bring about trouble. Not the cost of the varnish which, we suspect, deters anyone from using it, but the imaginary trouble in

applying it. We say imaginary because it is that rather than real, as we shall presently show. Before doing so, however, it will be well to say a little about the different varnishes that may be used for the purpose, and their characteristics.

The varnishes suitable for photographic purposes are of two classes—those which have alcohol as a solvent of the base, and those that have other solvents and other bases. In the "Almanac," pp. 960-62, are various formulae for negative varnishes, all of which are good, and are not difficult of preparation; but, we imagine, the majority of our readers who require a varnish in small quantities will prefer to purchase it rather than incur the trouble of making it for themselves, seeing that it is sold by all dealers, and at so low a price also, that a little of it goes a long way. Those of the alcoholic type have, mostly, shellac or sandarac—or a mixture of the two—as their base. These two resins are very different in character. The former gives a hard and somewhat tough film, while the latter gives a more friable one which can be rubbed up with the finger, yielding an excellent surface for retouching upon. But the former will withstand rough usage better. Both are very resistant of moisture. All spirit varnishes require the plate to be warmed when they are applied, otherwise they will "chill," that is, they will dry with a matt or dull surface instead of a bright one, and will also be less hard and resistant than if they were applied to a warmed plate. One of the cheapest varnishes is the "white hard" of the oilshops, the base of which is sandarac, diluted with about twice its bulk of methylated spirit, and its surface is easily abraded for retouching upon. Another equally cheap varnish is the "brown hard," the base of which is shellac, similarly diluted. Its surface is too hard to be rubbed up, so that a medium must be used if retouching upon it has to be done. Both these varnishes, while being cheap, are very resistant of moisture. The white hard is pale in colour, but the other is much darker, but this is of little moment, as in its diluted form the slight tint in the attenuated film only retards the printing to a very slight extent. Each of the above, like other spirit varnishes, as just said, requires the negative to be warmed for its application.

We shall now deal with varnishes that may be applied without the negatives having to be made warm. The first is dammar varnish, which was the one almost universally employed for the old collodion glass positives. We are not quite sure that it is still an article of commerce, but it is easily made by simply dissolving an ounce and a half or two ounces of good dammar resin in a pint of benzole. Like sandarac, dammar is a friable resin, but is a good resistant of moisture and its solution dries hard in a few minutes. Also its surface is easily abraded for retouching upon. Japanner's gold size diluted with one to one and a half times its bulk of benzole, also forms a good protection to negatives. The benzole evaporates quickly, but the film does not get really hard for some little time, gold size being essentially an oil varnish.

Celluloid—old celluloid films after the gelatine has been removed—dissolved in amyl-acetate forms an excellent varnish for gelatine negatives. It is very hard and thoroughly moisture proof, so that there is little fear with it of damp paper doing mischief to the picture. However, the cleaning off of the gelatine is troublesome, and this, with the cost of the amyl-acetate, when purchased in small quantities, is an item. It is, therefore, better to purchase the varnish ready made. At the shops where a feature is made of varnishes, polishes, lacquers, and the like, cold lacquers are now sold. These are practically celluloid varnishes. They may be had of various colours, and

colourless. The latter is an excellent negative varnish, that is, for gelatine negatives. It is, of course, of no use for collodion ones, as it would dissolve the collodion film. Its price is quite moderate, being only a couple of shillings or so the pint, and that quantity will serve for some grosses of small plates; no more suitable varnish for the purpose is to be desired. It becomes dry and hard in about half-an-hour, or even less if the temperature be warm.

In regard to the application of the different varnishes above alluded to, one thing that is imperative with all of them is that the gelatine film *must* be perfectly dry at the time the varnish is applied. With the spirit varnishes the plate should be very slightly warmed, just sufficiently so to take the chill off the glass. The varnish is then gently flowed over the negative, and the surplus drained back into the bottle. The plate should then be slowly made warm, indeed, quite hot, and in a few minutes, after it

is cold, it is ready for the printing frame. If the plate is made hot in the first instance, the varnish will not flow freely, and will be apt to run off at the edges, for it should be borne in mind that spirit varnish does not take quite so kindly to a gelatine film as it does to one of collodion. The gold size and celluloid varnishes may, with care avoiding streaks, be applied with a flat camel-hair brush, but it is much less trouble to flow them over, seeing that the brush has to be cleaned afterwards, to say nothing of the waste of material. Dammar varnish must be flowed over the plate cold, but it flows more freely over a gelatine surface than do the spirit varnishes, and owing to the volatility of the solvent it dries in a very few minutes.

These few notes, it is hoped, will remind some how little trouble is involved in insuring negatives against the effect, perhaps ruin, of contact with moisture or with damp paper in the printing.

## THE ART OF PORTRAITURE.

THERE is no branch of art that makes so wide an appeal as that of portraiture. The fact is very obvious, for it takes little consideration to understand that no other branch can possibly have such strong social claims upon the community. Moreover, these claims, extraneous to art itself as they are, are more likely to grow stronger than weaker in the future; of that every sign of the times holds a promise. Folks will always be interested in presentments of themselves, their friends, and their heroes. They always were.

### The Study of Art.

There is more than the mere difference of method that separates the artistic photographer from the portrait painter. In spite of various attempts at a confusion of terms—attempts undertaken by a few admirers of the former—the fact remains unshaken. Should there be a man here or there who claims to be both, he probably does not do so in a professional sense. The difference lies here: The portrait painter is a man who has studied art—its principles, its practice, its history, and its traditions. He has also studied enough of optics and chemistry to serve his purpose. The photographer, on the other hand, has studied—or, at least, we will be charitable enough to assume that he has—optics and chemistry, and sufficient of the principles of art to serve, as he hopes, his purpose. But this is not a fair exchange, even granting an equality of success in study on either side. The photographer is in the worse position, because to him artistic merit is incomparably more indispensable than is scientific knowledge in these days when the perfection of apparatus and material is not his responsibility, but that of the manufacturer.

### The Study of Masterpieces.

Does it not behove the photographer, then, amateur or professional, to come at that more elusive part of his equipment by any means in his power? The portrait painters of to-day have a quite reverential admiration and regard for their forbears in the art—the old masters of painting. To the most mature and catholic of them that regard is what Shintoism is to the Japanese. Photographers, however, have a way of thinking that they know better. Upon compunction a modern master may occasionally win a raising of the cap from them, especially if he be thrown in their way as an exhibition judge, or if he volunteer a tribute of praise to camera work; but the old masters are safe for sneers. It is a lamentable state of things; not to say suicidal. Presuming that old work is difficult of appreciation to the uninitiated, its lessons can, however, be learnt through the medium of the modern master who has

assimilated them, and it is here that a back door may be found admitting to artistic merit for all who have not had opportunities for systematic training through the more ordinary and elaborate portals. But does the photographer—a few exceptions apart—avail himself of this chance? Does he, as a rule, approach a painted portrait in that mental attitude which would elicit its lessons? It is to be feared that he does not. And yet they have always been painters willing to speak of the conviction and preferences, the expediences and principles, that experience, failure, and success have formed. From Leonardo downwards this has been so. The very last to take those into his confidence who will, is one whose name is familiar to all as a leading light in modern portrait-painting. Camera portraitists are recommended to give him a hearing, and to make an intimate acquaintance with the great works to which he points.

The Hon. John Collier has issued a handsome quarto\* that teems with valuable suggestions, besides many aphorisms and axioms that the photographer would do well to lay to heart. The volume is adorned with forty-one illustrations in colour and half-tone, of which the printing leaves little to be desired. It will astonish many, especially the votaries of a diffused focus and "sketchy" backgrounds, to learn that the author confesses himself a realist, and raises the cry, "Back to Holbein!" more pronounced antithesis to smudge and fuzz than Holbein it would be impossible to find. The Hon. John holds "that the first object of the artist should be to give faithful likenesses of his sitters, and these likenesses should be characteristic—that is, the sitters should be wearing the sort of clothes that they wear in real life, and should be in the sort of attitude that they are wont to assume. If there be any accessories, they should, at the least, be not incongruous. The background should represent a fairly likely place for them to be in, if it represent a place at all."

### The Fitness of Clothes to Surroundings.

Whilst realising that the question of costume is one of the greatest trials, he thinks that the temptation to clothe sitters in fancy and picturesque garb should, as a rule, be firmly resisted. The clothes of men to-day present the greater difficulty; but shooting clothes are often inoffensive, and some uniforms not impossibly gaudy. Furs are quite pictorial; but it always gives the author "a shock to see a gentleman sitting down complacently in his drawing-room in a heavy fur coat."

\* "The Art of Portrait Painting," by The Hon. John Collier. London: Cassell & Co. 10s. 6d. net.

he would certainly have taken off as soon as he came  
s. If he be so attired he had better be nowhere in parti-  
or else out-of-doors."

re is one point upon which the painter is evidently at a  
r disadvantage than the photographer, and this is the  
of indoor portraiture as opposed to studio work. It is made  
clear that the painting of portraits in an ordinary room  
with such difficulties for the artist as to make the prac-  
ill but hopeless. "Theoretically," says the author, "I  
like my sitters to be placed in an ordinary room, if pos-  
one of their own rooms, so that they should be portrayed  
ir friends see them." Against this, however, there are  
objections. To begin with, the light that falls from a  
higher than the ordinary dwelling-house window is more  
ing to the sitter, defining the features pleasantly without  
ting them. Further, it fatigues the sitter less than the  
which strikes more horizontally into his eyes. Then, as  
or painter finds it necessary to walk backwards from his  
the ordinary room does not possess distance or convenience  
h to enable him to judge his work properly. Again, if the  
stands he gets a quite impossible view of anyone sitting  
when all the perspective becomes absurdly steep. All these  
ions, however, melt before the photographer. His opera-  
not protracted enough for the eyes of the sitter to become  
the perspective troubles may be overcome by lowering  
mera, and as for the inferiority of the effect from a low  
of light—well, photographers can use a raised artificial

#### Backgrounds.

very pertinent observations are made upon the subject  
kgrounds. Since the author has to abandon perforce the  
backgrounds that a room might be expected to furnish,  
naturally very chary of mere inventions, but he has no  
ions to leaving out. In full-lengths there must be a floor,  
the floor seems to demand walls, and the walls look very  
without some furniture, so that we are almost driven into  
ucting at least a plausible room." Repeating "almost"  
n instances certain pictures, for example, the "Admiral"  
asqueez in the National Gallery, wherein a tangible floor  
off into space without seeming absurd.

hat most convenient article, the curtain, as a background,  
iso of the "unfortunately popular" tapestry, he urges a  
ninate use, since their very convenience has rendered them  
eyed.

at when all is said and done, perhaps the best background  
one that represents nothing in particular, only it must  
t the right tone, and I, for one, have the greatest difficulty  
enting this right tone." (Now the photographer has only  
his roll down, and there it is! No worry!)

to accessories, they must be natural. The sitter's own  
or one in which he feels and looks at home, is essential.  
n should not hold a book if notoriously he reads nothing  
he daily paper, and so on.

following, apropos of groups, are surely wise words:—  
harmony of line and mass and colour, which are the essen-  
of our art, unfortunately cannot be defined. Most people  
some feeling for them, and artists ought to, and generally  
assess this feeling in a specially high degree. It can un-  
edly be improved by practice, and by the study of fine  
ples; as to what are these fine examples there is a  
oncensus of opinion."

regret to state that Mr. J. Marsh, of Henley, formerly of  
Market Street, Oxford, died last week at Henley. He was  
eighty-ninth year. For a long period of years Mr. Marsh  
een a well-known and successful river photographer, and espe-  
of the regatta crews. Of late years the business has been  
d on by his sons.

The examples that appear in the book are fine enough in all  
conscience—"The Civic Guard" of Van der Helst, with twenty-  
five figures: the "Syndics," of Rembrandt, with six; and "The  
Company of St. George" of Hals, with eleven.

#### Trousers and Artificial Lighting

Upon the subject of artificial lighting Mr. Collier is parti-  
cularly hopeful, giving it as his opinion that the modern man  
is as well known to his friends by artificial light as by daylight,  
and that there is no reason why the daylight aspect of him  
should always be represented. Greater freedom in this direction  
is therefore advised for the courting of greater advantages.  
Of the use of cast shadows also he is an advocate, following  
thereby the tradition of Rembrandt, whom he thinks, neverthe-  
less, carried the dodge too far. For the suppression of a pair  
of trousers, "the most hopelessly unpictorial article of clothing  
that has even been invented," the cast shadow is the simplest  
means, but it must be one actually produced, and must not  
appear an arbitrary arrangement of light and shade. It must  
be given with "more or less of an edge, and with some definite  
form. But however the effect is produced it should look  
natural."

The author treats also the question of scale, deprecating heads  
larger or but little smaller than life. Whilst admitting that  
the larger the size the more vigorous and striking the portrait,  
he adds, "I dare say we should all be more impressive if we were  
a good deal bigger. But being the size we are, I think our  
portraits ought to represent us as of that size, and of no other."  
It is to be hoped, indeed, that those colossal masks that we  
occasionally see squeezing through a mount will pass away.  
They shock one like those expansive visages that bent over one's  
pillow in the days of nervous childhood. The undersized heads  
have the reverse effect; they are contemptible—mere mannikins  
—unless they are small enough to put the human standard out  
of mind.

As will have been seen from the quoted extracts, the author  
writes with firm conviction and honest forthrightness. Of  
"high falutin'" there is none, yet it would have been easy to  
drop into, with such topics as he finds. A wholesale discrimina-  
tion characterises all his opinions, and it is refreshing to hear,  
from one who has known the darlings of the critics, such sober  
and unbiased estimates as he makes of the art of Whistler, for  
example. Whistler without hysterics is something new in print.

A word should be said as to the three-colour reproductions of  
the pictures, since this venture is one of the first that takes the  
matter seriously enough to come forward with colour prints as  
"documents" for reference. On the whole, then, they show  
that steady improvement is still going on in this method,  
Moroni's "Tailor" being the best, perhaps, because it  
offered fewest difficulties. In some, however, the usual draw-  
backs appear; the "twang" of colour over all, and the hot out-  
lines that do duty for narrow shadows in flesh.

The author himself is not quite free from our carping. He  
frequently drops into the common error of using the word  
"technique" when the less generic one of "execution" would  
better give his meaning.

To conclude with his own last paragraph, so full of valuable  
admonition: "But if we are always trying to be clever instead of  
endeavouring to represent more and more truthfully what we  
see, we shall most assuredly degenerate into mannerism, which is  
the grave of art."

F. C. TILNEY.

THE Paris Photographic Salon will open a week later than the date,  
June 9, originally announced. The delay has been caused by the clear-  
ing from the rooms of the exhibition which is at present collected in  
the Palace de Glace, Champs Elysees. The Photo-Club de Paris  
has very generously given the outgoing exhibitors a few days' grace  
in which to remove their belongings.

## THE PHOTOGRAPHY OF COLOURED OBJECTS.

[A paper by A. von Hübl in "Photographische Korrespondenz."]

ALTHOUGH we can now sensitise our plates for any desired region of the spectrum, certain phenomena still appear in practice which point to an insufficient colour-sensitiveness or one that is not satisfactory for the particular purpose. In landscape photography, for instance, slopes covered with trees—in spite of ortho. plates and yellow screens—are rendered much too dark and wanting in detail, and in three-colour photography also complaints as to insufficient green sensitiveness of the plates is the order of the day.

This and similar phenomena cannot, however, be ascribed as a rule to insufficient or suitable sensitising, but to certain peculiarities of body colours which will now be explained.

As is well known, a coloured object always reflects a mixture of different coloured rays, belonging to a certain region of the spectrum, which, when they simultaneously strike our retinas produce a single colour sensation.

Fig. 1 shows a normal spectrum. The colours are in this in opposition to the prismatic spectrum of equal saturation, and, as will be seen, red and blue take up the most room, whilst yellow and blue-green are confined to quite a narrow zone.

From an object, which to us is yellow, all the rays are reflected which lies in those regions of the spectrum from red to green. The colours lying between red and yellow combine with those lying between yellow and green, in our eyes to form yellow. Therefore the colour appears intense and brilliant, which would not be the case if the object only actually reflected the small quantity of yellow which is present in white light.

### When Photographing Yellow.

The formation of the compound colour, "yellow," from the above-mentioned components is easily shown by a colour top. For this purpose a sheet of cardboard is painted as shown in Fig. 2—so that the size of the coloured sectors corresponds to the extension in the spectrum—and then set rapidly whirling. This screen will then appear of an even yellow colour, for the coloured sectors combine, and we see precisely the same as if all the colours simultaneously acted on the retina. The colour of a yellow object is therefore principally caused by the red and green rays reflected by it.

A red object of the colour of vermillion reflects as shown in Figs. 1 and 3 a much narrower zone of the spectrum. The mixture of rays can only include red, orange, and yellow, for with the addition of the neighbouring colour, "yellow-green," a yellowish orange would result.

Fig. 1.

The mixture of rays emanating from a yellow object only differs therefore from the form a vermillion object by the presence of the green rays. From this fact the following conclusions may be deduced:—

(a) In order to reproduce by photography a yellow object light, it is necessary to sensitise the plate for the yellow rays of the spectrum, it will be sufficient also if it is sensitive for any colour between red and green.

(b) In order to obtain vermillion and yellow equally bright, the plate must be sensitive for yellow, orange, or red.

(c) Yellow will be reproduced bright and red dark if a green sensitive plate is used; inversely, however, it is not possible to

photograph yellow and vermillion so that the former appears bright and the latter dark. This requirement is often advanced in the colour work; that it cannot be fulfilled may be compared to the problem of photographing black lighter than grey.

A green object reflects with the green, also the yellow green, blue green rays, and an analogous colour mixture gives us the colour top screen shown in Fig. 4. The spectral zones, Fig. 1, which come into play, are also short, and a lengthening of the same is possible, for the adjacent colours, blue and yellow, are not complementary, and combine to form white, and their presence weakens obviously lower the saturation of the colours.

Fig. 2.

Fig. 3.

The rays reflected by a blue object consist chiefly of spectrum blue strengthened by the blue, green, and violet rays; reddish blue reflects small quantities of the red rays, and by gradual increase of the latter the colour changes from blue to violet and purple and red.

Perfect colour brilliancy is wanting in most of the saturated colours for they are saddened by the admixture of more or less black.

Yellow is the only exception in this respect, whilst the pure vermillion, emerald green, and ultramarine, always show a certain tinge of black. But such pure colours are rarely met with in nature or in pictures.

This fact can be easily proved by placing the coloured object on white paper and looking at it through a glass of the same color. The colour will then completely disappear, and the object shows more or less of a grey appearance, which is produced by the proportion of black in it. If this grey is compared with a scale of greys of known value the ratio of black in the colour may be numerically determined.

Fig. 4.

Fig. 5.

What a considerable proportion of black there is in certain colours which are considered as tolerably pure, may be learnt from the following experiment. A colour template coated with a mixture of ultramarine and chrome yellow, and a smaller one painted with as far as possible, a pure green, such as an aniline dye, combined with opaque black, should be arranged as shown in Fig. 5.

When the two screens are rotated together to produce the same impression, the sectors of pure green and black must be about 1:2.

From this experiment one must conclude that the mixture of ultramarine and chrome yellow consists of one part of green and two parts of black, and as the pure green used for comparison also contained some black the proportion is still greater. Most painters

show a somewhat similar high proportion of black and almost no colours of nature also.

Under such condition it is indeed natural that the green in a plate, for instance, can never under any conditions be photographed bright and white. If a plate is strongly sensitised for green, yellow, and blue green, and a narrow green filter be used, such a pigment can never be brighter than a grey with an equal amount of black in it, thus a grey which consists of two parts of black and one of white.

It is explicable why the ortho plate frequently does not give the expected advantage, why in three-colour work the red printing is frequently said to be defective as regards density in the blue.

The cause of this obvious fault does not lie in the sensitising of the filter; it should obviously rather be looked for in the ortho plate, the blackness of the colour.

#### The Colour Chart as a Test Object.

These peculiarities of colours must also be kept in mind when the properties of a photographic plate are to be determined by photographing a coloured chart.

The customary method at present of testing colour-sensitive plates

is by means of a colour chart. Further, the colours must be of the same purity and equal saturation.

A colour chart issued with this paper ("Korrespondenz") is composed of a central white circle—round this a blue square marked "blau," at the top is a yellow "gelb" which, when mixed by sectors of 180 degs., gives with the blue a neutral grey, and at the bottom are two squares, green, "grün," and red "rot." The red, green, and blue colours are symmetrically placed in the colour circle given in von Hübl's book on three-colour work, and when combined by rotating sectors produce also a neutral grey.

The yellow and red must be slightly darkened with black in order to fulfil these requirements, so that a fairly equal purity of all colours, that is an equal proportion of black, was obtained. Round these coloured squares is placed a grey ground which has the same proportion of black as the colours, so that in photographing this chart in no case can any colour appear lighter than this grey. The density obtained in the yellow and blue sections shows the ratio of the total colour-sensitiveness to the blue sensitiveness of the plate. These two pigments here play the same rôle as the yellow and blue filters as used by Eder in his colour sensitometry.

means of the spectrograph is indeed theoretically free from error. It gives, however, only very uncertain conclusions as to the behaviour in actual practice. For this reason a colour chart has again been recently recommended by Dr. Aarland as a test object.

It may be advanced against the colour chart that it can only prove the behaviour of the plate to a mixture of coloured lights, but this is exactly what the practical worker wants. It is of little interest to know whether the plate is sensitive to wave length 590 or 610; he wants to know how the plate will behave to various coloured objects, whether it can also be called colour-sensitive without a yellow screen. What intensity of filter is necessary in order to reproduce reds and yellow in a given luminosity ratio, whether it will reproduce reds, light, and so on.

Such and similar questions can be answered with much greater certainty with a chart than a spectroscope.

The colour chart must, however, be chosen in a systematic manner. It must contain certain pigments, as the conception of red, green, and blue, and so on, is undetermined, and it depends upon the sub-

jective conception. In order to learn better the peculiarities of sensitising, especially with plates of low colour-sensitiveness, a yellow screen is used which possesses a saturation equal to the yellow field of the chart.

The accompanying results were obtained with different plates. The ordinary plate gives the blue about the same luminosity as the grey border, all other colours almost black. The very slight action of the green and yellow, but which is plainly distinguishable in the negative, is explained by the fact that these colours reflect the adjacent blue green rays, and the plate is somewhat sensitive to these rays. The red also appears to have some action because this pigment reflects a very small quantity of the violet rays. A collodion plate shows a slightly different appearance, for its sensitiveness does not extend into the blue green but reaches further into the violet. The red square is therefore only faintly but distinctly exposed, whilst green and yellow are clear glass.

A commercial ortho. plate shows without a filter almost no colour-sensitiveness, but with a yellow filter it gives the yellow and green dense and the red very thin. If the exposure for an ordinary plate is assumed to be 1, the ortho plate with the yellow screen requires an

exposure of 30. The exposures above the prints are also given in the same way.

A plate bathed with pinaverdol, as described on p. 148, "B.J.P.," February 23, 1906, shows a much higher colour-sensitiveness, as with a yellow screen it only requires four times the exposure. Pinaverdol is an excellent green sensitiser; its action extends further towards the yellow than to erythrosine, as will be seen by the reproduction of the red square.

Pinacyanol reproduces red and green of almost equal luminosity; yellow brighter for this pigment reflects the red and green rays also. With a yellow screen the exposure must be increased four times, and then the three squares are lighter. Their relative luminosities, however, remain unchanged, and the blue obviously appears as black.

Pinacyanol sensitises to an equal degree for red and green, and by the addition of a small quantity of a yellow dye to the bath the blue may be so damped that these three pigments will appear of equal luminosity. Such a plate will always reproduce yellows brighter than red and green, as can be easily understood from what has already been said. In orthochromatic work, as in the taking of painting and landscapes, it requires only a very bright yellow filter

to reproduce all colours in their relative luminosities, and it is a suitable plate for three-colour work. It has been frequently stated that this plate cannot be used with the green screen. I cannot agree with this statement, for not only this chart, but a series of tests in blue, green, and yellow green pigments, have proved that pinacyanol gives the same results as the best green sensitiser.

The last chart reproduction shows a characteristic pure red sensibility, and on the other hand the high colour sensitiveness of a colour emulsion. Without any colour screen, dicyanine collodion emulsion reproduces vermilion and yellow almost like white, and requires therefore about the same exposure as a good sensitised gelatin with a yellow filter. The slight deposit in the green square shows that the plate is almost entirely wanting in green sensitiveness.

The colour chart is also useful for adapting colour filters for the colour work. A green filter, for instance, which is used for the colour system, "crimson, blue, green, and yellow," must be so chosen that the red and blue squares are of equal density and that of white, like the grey of the chart.

From these examples it ought to be seen that a systematically composed colour chart is of eminently practical value for all photographic work, in which colour plays a part.

## THE PHOTOGRAPHIC CONVENTION.

Last week we reminded our readers of the approaching Convention of the United Kingdom. The time draws near for the opening of the week at Southampton, which will witness the coming of age of the Convention, and will mark, so we believe, the assumption on its part of duties and responsibilities which in the recent past it has not regarded quite as seriously as it might have done. In every way the Southampton Convention promises to be what such a gathering should be, i.e., representative of photography in its industrial, scientific, pictorial, and recreative aspects. We have on a former occasion drawn attention to the programme of demonstrations, papers and excursions which await the visitor at Southampton, but as the memory of man is apt to let these things escape him, and as the arrangements are now at the stage of completion, we may be allowed to summarise the chief items in the Convention's programme for the benefit of those who may not have finally decided upon becoming one of the Conventioners. Perhaps no greater testimony to the success of previous conventions can be adduced than the fact that the Convention habit is one not easily shaken off, so that year by year figures which were first seen at the early meetings have turned up regularly, and will continue to turn up whilst the Convention continues to draw together a large body of men and women all interested in whatever makes for the advancement of photography.

### Papers and Lectures.

"The Differentiation of *Bacillus*, *Coli Communis*, and *Bacillus* Typhoons, by Means of the Photographic Plate." By Dr. Walter C. Stevenson.

"Is the Photographic Film Ionised on Exposure?" By Mr. Herry Thrift, B.A.

"Useful Negatives from Poor Ones." By Mr. C. H. Bothamley, F.I.C.

"The Ordnance Survey Department." By Colonel S. C. N. Grant, R.E.

"Old English Manners and Customs." By Sir Benjamin Stone.

"Clouds." By Mr. A. W. Clayden.

"Combination Printing." By Mr. A. Horsley Hinton.

"The Application of Cinematography to Natural Science." By Mr. F. Martin Duncan.

"Colour-Photography Up to Date." By Mr. E. J. Wall, F.R.P.S.

"Cinematography in Colours." By Captain Lascelles Davidson and W. Friese Greene.

### Visits and Excursions.

Cowes, Carisbrooke, and Osborne House.

The New Forest, Bolderwood, etc., etc.

Winchester, and St. Cross.

Netley and Romsey Abbeys.

The Ordnance Survey Department.

An American Liner on the Morning of Departure.

Mention should also be made of the unusual yachting facilities at Southampton, and of the fact that the President's "At Home," on the Wednesday afternoon, will take the form of a yachting party. Mr. Humphrey's leisure for many years has been spent abroad yachting, and, without anticipating the announcement of his plans for the entertainment of the Conventioners, on July 11, it may be said that the occasion will mark the zenith of enjoyment in what promises to be a most enjoyable week. The Earl of Crawford also hopes to have his yacht, "Valhalla," at Southampton during Convention Week, and to take part in the meetings.

### Demonstrations and Exhibits.

The Platinotype Co.—A large show of platinotypes, including a sepia platinotype paper with glazed surface; developing demonstrations, artificial light portraiture in a spacious annexe.

Kodak Ltd.—A large show of "Kodakery" Prints and enlargements, developing machines, demonstrations, etc.

The Autotype Co.—Carbon work in all its branches; developing demonstrations, including three-colour carbon.

Messrs. J. J. Griffin and Sons.—Specialties—pictures on velvet, demonstrations, etc.

Mattos Paper.—A fine show of pictures on the various kinds of Mattos paper, demonstration of toning, etc.

Wellington and Ward.—Screens, showing results on their papers and plates. Demonstration of toning bromide prints.

A. and L. Lumière.—Three-colour work.

J. H. Dallmeyer, Ltd.—Large show-case of lenses and apparatus. Photolinol, Ltd.—Show of results on bromide linen; "Anglo-sepia" platinum paper enlargements. In the balcony, studio demonstrations of portraiture by the Cooper-Hewitt electric light.

The Aerograph Co.—Finishing by means of the Aerograph, Mr. C. L. Burdick, who it is hoped will show the utility of apparatus for producing stencil postcard colouring.

Carl Hentschel, Ltd.—Will have two large screens of three-colour block work, etc.

Fuerst Bros.—Will demonstrate pinatype at the Conversazione.

The exhibition will be open free to the public on Tuesday, Wednesday, Thursday and Friday, from 2 till 5. The evening meetings, lectures, papers, receptions, conversazione excursion, yachting party, visit to the Ordnance Survey Department, etc., are restricted to members of Convention only.

To this list of attractions must be added the exhibitions of studio photographs, of work by the Southampton Camera Club, of scientific and photo-micro photographs, and other prints dealing with

photography in its scientific applications. The whole of the local arrangements are in the hands of a committee of which Mr. W. R. H. Hill is Chairman, and Mr. S. G. Kimber, Secretary. Reports speak hopefully of a large and enthusiastic meeting, and it is expected that many who have never hitherto taken part in Convention

gatherings will this year select the Southampton meeting as an auspicious occasion of meeting and making many friends. The general honorary secretary, Mr. F. A. Bridge, of East Lodge, Dalston Lane, London, N.E., will answer any enquiries from those anxious to become members.

## FOREIGN NOTES AND NEWS.

### The Action of the Ultraviolet Rays.

JOE points out in the current number of the "Photographisches schenblatt," that the ultraviolet rays play a considerable part in forming the image. The greatest photographic action lies between 345 and  $\lambda$  395. It is less on slow plates and more strong on rapid ones. With the latter the action is rather less than the blue and more than the green rays. Practically half the photographic action of white light is to be ascribed to the ultraviolet, and it acts more strongly on ortho. plates than on ordinary.

Acridine yellow, wool yellow, and canary yellow, which may be added to emulsions to diminish the action thereon of blue rays, will be found to lower very little, as they are actually strong sensitizers for the ultraviolet.

As already pointed out, the ultraviolet acts more on colour-sensitive plates than on ordinary, and thus it is quite possible to obtain results in practice which are not consonant with spectrographic tests. Thus, for instance, an alizarine red lake may not only reflect red and violet, but also the whole of the ultraviolet, and it would therefore give a fairly dense image even on a yellow-green sensitive plate, for the action of the ultraviolet at  $\lambda$  375 is almost as great as that of the orange rays.

Stenger has shown that an erythrosine bath plate shows as much density, 2.57 in the yellow as in the blue at  $\lambda$  450, but when photographing a chart, the blue pigments will always be rendered lighter, cause to the action of the blue is added a further density of 1.68 to the ultraviolet.

To absorb the ultraviolet, a yellow screen must be used, but care must be exercised in the choice of the yellow, and it is better to use 1 per cent. solution of quinine sulphate in a liquid cell of 1 cm. thickness (or a gelatine coated plate soaked in a saturated solution of aesculine.—Eds., B.J.P.).

### The Nature of the Developed Image.

LÜPPO-CRAMER publishes in this month's "Korrespondenz" some experiments he has made on this subject, a continuation of previous work in which he showed that nitric and chromic acids, and persulphates dissolved the image but left a yellowish brown substance behind. He now finds that:—

1. A 2 per cent. neutral or faintly acid solution of permanganate of potash dissolves the silver, leaving behind, after the removal of the manganese oxide with bisulphite, a brown image. If the permanganate solution is strongly acidulated with sulphuric acid no visible image is left, and yet a vigorous negative can again be obtained with physical development.
2. A 5 per cent. solution of ferricyanide of potassium, converts the image into white ferrocyanide of silver. If this be fixed in hypo, a faint yellow image remains. If, however, ferricyanide and hypo are used together, the image is completely dissolved and cannot be again physically developed.
3. When bleached with cupric chloride, and then fixed, there is no visible image left, but the negative can again be physically developed.
4. Bleached with bichromate and hydrochloric acid, there remains a faintly visible image which can be physically intensified.
5. Bleached with bromine water, the whole film becomes an intense yellow, but can be decolourised with bisulphite. If the white image is fixed in non-actinic light it cannot be again developed. If fixed in daylight there remains a visible image.
6. If a solution of iodine in potassium iodide be used, there is no developable image left even when it is fixed in daylight.
7. Ferricyanide of potassium with cyanide destroys any developable image.

If the image after treatment with chromic acid is immersed in

hypo a developable image remains, but if it is immersed in an acid hypo solution for an hour or two every trace of an image disappears. From this it is obvious that the simultaneous presence of an acid and a solvent of the image is required. A test with a 10 per cent. solution of ammonium sulphocyanide acidulated with sulphuric, nitric, hydrochloric, or citric acid, also showed that the whole of the image dissolved.

The author comes to the conclusion that the finished negative consists of two components:—(1) That part which is soluble in chromic and nitric acids, etc., and which probably consists of pure silver; and (2) the second portion which is left behind in the above treatment. This latter, the author thinks, may be a kind of solid solution of silver in silver bromide, or subhaloid.

### The Gradation of Orthochromatic Plates.

DR. STENGER, in a series of papers which have lately been appearing in the "Zeitschrift für Reproduktionstechnik," has dealt with the colour rendering by orthochromatic plates, and obtained the density curves for practically every ten wave lengths from 500 to 690 with increasing exposures. The articles do not lend themselves to useful abstraction, but at the close the author summarises his results as follows:—Behind the three filters for trichromatic work approximately parallel curves of density are obtained on colour-sensitive and ordinary plates, and with regularly increasing exposures regular increase of the density is obtained. A colour-sensitive plate does not show any extraordinary difference in its behaviour to light of different wave lengths. If the filter is adjusted to the plates so that the different maxima of sensitiveness are used, the result is a considerable shortening of exposure. If, on the other hand, the filter is not carefully adjusted, then the only result is that a longer exposure must be given, but the colour rendering does not suffer.

If similar gradations are required, then the same kind of plates must be used for all three exposures. Apparently, there is no constant which will enable one to say what will be the gradation curve of a sensitised rapid plate from a knowledge of the curve of the unstained plate. With transparency emulsions, staining the plate produces greater hardness as a rule. Comparative experiments with fast and slow plates have proved that the latter are more suitable for orthochromatising by bathing than the former, and better colour rendering is obtained. A further advantage of the use of slow plates is that they are much less liable to fog. The author's experiments have proved that the well-known fact that the maximum optical absorption of a dye is not coincident with the maximum of sensitiveness, but that the latter lies, as a rule, about twenty wave lengths nearer the red.

### Marginal Fog.

Dr. Homolka, continuing his researches on this subject (B.J., December 22, 1905, p. 1,008), has tried the action of different bromides. To every litre of emulsion 0.01 gramme molecules, corresponding to 0.8 g. of bromide, was added; for potassium bromide the quantities were: lithium bromide 0.87, ammonium bromide 0.98, sodium bromide 1.03, potassium bromide 1.19, rubidium bromide 1.65, and caesium bromide 2.13 grammes. Lithium bromide gave the least extension of marginal fog. Hence it is advised to add to the perfectly washed emulsion 0.87 grammes of lithium bromide per litre.

### The True Cause of the Formation of the Latent Image.

Whilst it is generally known that a latent image may be obtained on a sensitive film by various means, probably few are aware that the actual agent in every case is ozone. We must confess that this was new to us till we read a reprint of an address delivered by Benj. W.

Sands before the Photographers' Association of Missouri in 1905. He first convinced himself that ozone was the active agent, and then spent ten years in study and experimenting to determine the truth or falsity of his discovery. So far as we can see, the only proof he has is that he obtained a silhouette by the ozone generated from phosphorous. This is confirmed by the fact, according to the author, that "all the developers used to render the latent image visible, of which pyrogallol, eikonogen, ferrous sulfate, and potassium cyanide, are representative, are powerful absorbers of oxygen." A further proof is that iodide of starch paper, when exposed to light under a negative gives an image, thus "proving that white light creates ozone in proportion to its intensity." One must not, of course, advance the statement that the image is due merely to the liberation of iodide from the potassium iodide and its combination with starch. The author gives a list of no less than thirteen different ways in which a latent image may be produced, of which we give a few—lightning, X rays, light stored upon sugar, glow-worm rays, breath figures, N rays, and, of course, radium—and then says, "these numerous examples of the production of the latent image, both by direct and indirect radiation, serve the double purpose of showing the many ways by which the latent image can be produced, and of proving that all the various causes of production are but the different phases of one, and only one form of energy. Because, first—the latent photographic image is produced by ozone. Second ozone is always the product of oxygen plus magnetism. Third, any objective phenomena which can be photographed, proves the existence of a magnetic radiance therefrom, either direct or reflected. There is one method that the author does not mention, and we suggest that as a latent image can be produced by pressure the pressure causes magnetism which, plus oxygen, gives ozone; hence the latent image. Q. E. D.! On the subject of ozone the author seems a little hazy for he still ascribes the blue colour of the sky to ozone. Lord Rayleigh's researches notwithstanding. Again he says: "On account of the specific magnetism of oxygen varying inversely as the temperature, it is obvious that as the temperature decreases the quantity of ozone increases. For this reason the formation of ozone by light gives us the greatest amount in winter, and we find that when the atmospheric ozone is at its maximum, so also is the photographic action of light." Apparently we shall have to revise all our exposure tables.

#### A New Era in Photography in Colours.

The above extract from Mr. Benj. W. Sands's paper, we think, makes for thought and new lines of experiments by our photochemists, and we present yet another abstract which will set all those

who are interested in colour and colour photography experimenting on new lines. He informs us that what we have to search for is colour sensitizers whose combination with ozone corrects the great oxidising power of the blue end, or increases that of the red, because ozone is formed under all the colours of the spectrum, but most of the ultra-violet. "Photographs in their natural colours have been the aim of all photographic chemists, but up to the present time one has been successful in producing permanent prints except by the multiple-film process. Lippmann's process, by the 'interference' of light waves added much to our knowledge of thin films and the subject generally. But to-day marks a new era in this subject. From this time we will not have to experiment the dark to finally stumble on some chemical responding to all the colours of the spectrum. We can select such chemicals as are oxidized to the proper colours by ozone, or the reverse process, deoxidized, as I firmly believe that in the very near future we shall have photographs with all the colours of nature correctly rendered, and the process will be even more simple than ordinary photography."

#### A New Paper.

MM. Lumière, in the current issue of their "Revue Trimestrielle" give notice of the preparation of a new printing-out paper, which they call "Takis," samples of which will, no doubt, reach us in due course; but the reason for our noting it is that it involves, so far as we are aware, a new principle in the manufacture of printing paper. The paper is a P.O.P. containing excess of silver nitrate, as well as a developing agent, and it is only necessary to expose the same under a negative for a short time and then immerse in water, where physical development takes place. The novel point is the incorporation of a reducing agent with the emulsion, and the authors state: "The addition of the developer to an emulsion produces in very short time the reduction of the soluble silver salt. We have overcome this trouble by the addition of sulphurous acid, either to the emulsion or to the developing agent which we add to it. Here is a typical example of how we prepare our paper with gallic acid: Make 20 per cent. solution of gallic acid and add 10 per cent. of aqueous sulphurous acid. If, in the dark, 50 per cent. of this solution is added to a gelatine chloride emulsion, there is no difficulty in making a coating the emulsion." Mere immersion of the paper in water after isolation, develops the image, and the advantages of a printing-out and a development paper are combined. There is said to be a good range of gradation and great variety of tones, as the paper may be merely fixed, or toned with gold, either in separate or combined baths, or with platinum.

## DIFFRACTION GRATING REPLICAS.

In a previous paper<sup>1</sup> the writer described the process in use by him for the manufacture of replicas of Rowland's plane diffraction gratings. The present note is a description of a modification of that process, which offers a simplified method of producing good casts.

#### A Simplified Process of Making Replicas.

The original grating is flowed with the amyloacetate collodion and dried in the manner previously described; it is then placed in distilled water until loosened by contraction, and wiped dry. The stripping is performed as usual, and the edges of the cast are trimmed with sharp scissors close up to the ruled surface. This trimming should be done while the replica is held by the forceps, as it is strongly electrified by the stripping, so that minute particles of dust are attracted to the surface of the cast, and adhere thereto, being removable only with difficulty. A perfectly clean and polished glass plate is then flooded with filtered distilled water; and, while the plate still holds a little pool of liquid, the film is gently lowered into contact, carefully centered, and the plate is tilted up. A very gentle even pressure by the velvet rubber frees the cast from surplus water, and the edges are immediately cemented.<sup>2</sup>

The mounting may be either face up or down, as may be desired. After the edges have been cemented down, the mounted replica may be dried by heat, beginning gently and increasing gradually until a temperature of about 75 deg. C. is reached. In this way the film of water between the glass and the replica is driven off, the film being slightly porous.

If the replica has been mounted face down, it may readily be cemented under a covering glass, following the idea advanced by Ives. Care must be taken, however, that no particles of dust or other foreign substance have found a lodgement either between the glass and the replica, or in the film itself during the drying, as this will inevitably cause trouble by puncturing the replica and allowing access to the cementing balsam, which, gradually working through the most minute hole, and filling up the grooves, destroys the grating.

Since the publication of the previous paper the author has been informed that the deterioration of the Ives grating alluded to there is due to this cause, and another grating since obtained shows no sign of deterioration. A correction is also due with reference to

coating, which in my (his) opinion is quite unnecessary." He does not indicate whether or not any other medium is used in this connection.

This idea of mounting by the water method first occurred to the present writer about one year ago, and some slight amount of experimental work was performed thereon at that time. However in the beginning of September, 1905, the work was again taken up and carried through to completion in October: a written statement of the process was made and attested on November 2. In the event of further information confirming the similarity of this water method with that pursued by Mr. Thorp I cheerfully accord to him the priority of use of this process.

<sup>1</sup> "Astrophysical Journal," 22, 123, 1905. (Reprinted in "B. J. P." Nov. 24, 1905.)

<sup>2</sup> Since the writing of this present note there has come to hand "Nature," of November 23, 1905 (73, 79) containing a brief article by Mr. Thorp, somewhat in the nature of a reply to my former paper. In this article Mr. Thorp states that he strips and mounts "in a similar manner to Mr. Wallace, but leaving out the gelatine

patent, as it now appears that no patent was applied for. The previous statement was based upon information the writer had reason to regard as authoritative.

### Some Advantages of Water Mounting.

Water mounting by what may be termed the water method, in distinction to the former gelatine method, one eliminates at once every slight difference in refractive index between the replica and mountant; true, the difference still exists between the replica and the glass itself, but this may be readily overlooked. Experience shows that, although theoretically open to objection, yet practically, so far as definition is concerned, it is an entirely "negligible quantity." In any event, the similarity in refractive index between film and mountant (or cement), when adjusted for light of certain wave-length, will not be similarly identical throughout the spectrum. In this connection it may be noted that if a replica be mounted face down upon the gelatine-coated glass, and dried, approximation to a refractive index of the replica is so close that in ordinary daylight the grating effect disappears, and diffraction colours are entirely absent. If examination be made, however, in a spectroscope, with a slit and a concentrated beam of light, then very faint first-order spectra are discernible.

Further experimental work was undertaken with the object of determining whether the shrinkage effect was complete with the first part of the process (the stripping) or was continued during the course of drying. The result of these experiments confirm the latter view.

### Shrinkage Measurements.

Measurements were made upon replicas taken from a four-inch and six-inch grating, respectively, which were stripped and mounted under varying conditions, viz.: (1) preliminary bath in water, "sprung" off, and peeled dry; (2) floated off entirely under water; and (3) with prolonged soaking in water. The measurements were made (a) while wet, (b) partially dry, (c) thoroughly dry; (d) dried by heat; and (e) at normal temperature; (f) water mounting and (g) gelatine mounting; also (h) water mounting, cemented edges, (i) water mounting, uncemented edges. Mean results show that there is a measurable contraction during the drying of 0.016 mm. in 55.0 mm. The particular benefit, therefore, arising from the use of a preliminary coating with gelatine lies in the fact that once the replica is mounted thereon it dries without further shrinkage, the gelatine itself drying on glass without contraction in area. This latter point was determined separately by a series of measurements, for which the writer takes pleasure in acknowledging his

indebtedness to Miss F. A. Graves. These measurements upon wet and dry gelatine films were made with the object of determining any positive shrinkage between the two states. The results obtained show that there is no measurable difference observable, the actual mean being

wet = 7.050 mm.

dry = 7.028 mm.,

the difference of 0.002 mm. obtained being less than the probable error in setting.

### Effects of Temperature and Pressure.

In a series of experiments made upon the influence of temperature upon the collodion film during the time of "casting," it was found that an increase over 21 deg. C. would cause the replica to dry with a more or less matt or reticulated surface. This reticulation increases with the temperature. Lower temperatures varying down to 6 deg. C. appear to exercise no influence upon the film.

Contrary to expectation a pressure of 200 lbs., continued for ten days, appears to have no direct effect upon the replica. It was supposed that such a continued pressure would result in either a flattening of the ruling, or at least in a changed shape of groove. Careful examination in a spectrophotometer, however, does not show any difference between the half which was subjected to pressure and that which was not, each half being covered by opaque paper, respectively, when tested.

Through the courtesy of Mr. T. Thorp, of England, the writer has been presented with a grating replica from a 14,438 ruling, and in a letter accompanying the same is informed that the present method of preparing and mounting the casts has been much improved from that in use by him formerly, the air-bubbles (referred to in my former paper) being now entirely eliminated. The replica certainly bears out the statement, being very free from such imperfections and presenting a very clean and brilliant appearance. Mr. Thorp further states that he does not use a preliminary coating with oil before flowing the grating, but makes use of a method "very little different from" that described by the writer in his previous paper.<sup>5</sup>

ROBERT JAMES WALLACE.

<sup>5</sup> Information upon this point was taken from an account of patent specification, (No. 11,466 1899, T. Thorp) dealing with an improvement on Professor R. W. Wood's diffraction process of colour photography, in which occurs the following statement: "A method, non-photographic, of reproducing gratings by smearing the original with a thin oil, such as watchmakers use, and pouring a celluloid solution upon it, allowing it to dry and pulling it off, is also claimed." ("Photography," August 2, 1900, p. 514).

## PHYSICAL CHARACTERISTICS OF RELIEF ENGRAVINGS, ESPECIALLY RELATING TO HALF-TONES.

(A Paper by N. S. Amstutz in the "Inland Printer.")

"The second number" is properly retrospective to a considerable degree. It is always a satisfaction to look back and, even from an advanced position, note the various steps that have led to such position. To be self-sufficient and wholly satisfied with the immediate present is not evidence of a proper breadth of development or indicative of a national growth in the technic of any subject.

The master of the engraving field, before the advent of photo-engraving, was the xylographer, or as we know his art, the wood engraver. He had held the illustrative field for years unchallenged. He also called to his aid photography, in the latter days of his greatness, to directly copy his commercial subjects on to the wood block. The expert technic of the engraver translated the tone values of the subject into printing points or lines by grooving the surface of the block with a V-shaped tool in variable directions at variable lines per inch and to variable depths. On the variable depths, to a considerable degree, he was dependent for his medium of interpretation in which to translate the interrelated effects of light and shade.

In looking backward from present-day practice, wherein the formation of depressions on a printing surface is guided optically through

the interposition of a screen and sensitive plate in the camera and the resultant negative and acid resist print on metal, one is reminded of the marvellous skill of an expert xylographer. It is a matter for congratulation that the popular magazines are furnishing their readers with art prints from wood engravings. By this means the younger generation can know of the beautiful effects produced by this now little understood craft.

The result when an engraver only perfunctorily grooved a block was not always as happy as when an artistic instinct was combined with mechanical technic to control the relation of groove to ridge and of dot to white and black. Xylographic reproductions—artist-produced—are analogous to artistic reproduction by means of dry-point etching, each depending on individual skill.

Because of the fact that there was no camera or other intervention between the artist mind and the finished result, one finds overwhelming characteristics of breadth of treatment, vigour of conception, and brilliant or sombre interpretation that will for all time differentiate the actual personal production of a master mind from mere duplication by extraneous means.

Enough for this digression. Present-day methods of commercial and scientific illustration do fill a large want in a most satisfactory and efficient manner. The demands of modern conditions are such

\* The previous paper from the "Inland Printer" was reprinted in the B.J.P. for April 27.

as to require the multiplication of hands; this is attained by the camera and its accessories.

The closely related methods of lithography, photogravure, and colliotype in all its various guises, occupy a field distinctly their own, so they can not now be referred to, except in passing.

### Automatic Engraving.

In wood engraving the eye and intellect of the operator controlled the graver by a greater or less elevation, or more or less pressure thereon, to form grooves of varying depth and width, and, as stated, at variable distances apart and in various directions. The "control" was the skill of the operator. Among some of the first attempts in the direction of automatic control may be mentioned a mechanical method of 1881, patent filed October 25, 1880, which used a suitable sliding base, under the control of a hand-operated feed screw. On this base was secured a carbon relief, and adjacent thereto a material on which the engraving was to be made. Above the base was a support for a tracer and graver slide. The tracer rode up and down over the carbon photo as the slide was moved backward or forward, its movement was transmitted to the graver, which was V-shaped, through a pivoted frame mounted on the slide. This frame was spring-pressed so as to hold the tracer and graver in working relation. At the end of each rearward and forward movement the base was moved the distance of one line so that at the next stroke of the slide a new portion of the photo relief will be passed over and another line engraved. The up-and-down movement of the graver made it cut deeper or shallower in the metal sheet, in parallel lines, thus engraving the photo. The photo-relief did the "thinking" as to where a deep or shallow groove was to be engraved.

### The Ives Process.

Another method, of 1881, patented by F. E. Ives, filed August 9, 1880, also utilised photography, in that a photo-relief was made and a plaster cast taken therefrom. On this plaster cast an ink impression was made from a block of elastic material. The face of this block was serrated by V grooves. It was inked and placed on the plaster cast and subjected to a uniform pressure. Where the surface of the plaster cast was slightly raised, the pressure was greater than in the depressions, and consequently the V ridges, being elastic, were flattened more or less, thereby producing a variable breadth of impression. When the elastic block was removed, the white surface of the plaster was covered with parallel black lines of varying widths. This was then photographed as though a line drawing, and subsequently etched. If the face of the elastic surface was serrated by intersecting grooves, the impression was one of varying-sized dots, instead of parallel lines.

A third method, of 1891, was electrical; it also utilised a photo-relief. A tracer was pivoted to a traversing carriage and caused to ride over the photo-relief, which was secured on an adjacent drum. This tracer controlled resistances in an electric circuit, which through the control modified the movements of a magnet that actuated a V-shaped graver, suitably pivoted on another traversing carriage adjacent a second drum, on which was placed a wax film. The two drums rotated synchronously and the graver formed V grooves in the wax of varying widths and depths. The wax film was prepared for printing by making an electrotype therefrom. By the use of stronger currents, engraving on metal sheets became possible.

The difference between this method and the first one named is that one was electrical and the other mechanical. This mechanical process encountered serious difficulties in that the tracer riding over the photo-relief received all the engraving stress on its minute tracing point. This played havoc with the essential element of the process. The engraving stress reacted on the tracer and caused it to groove the photo-relief, destroying its translation.

A fourth device, of 1883, also electrical, utilised an ordinary negative, by causing it to control, in conjunction with a source of light, a selenium cell. This varied its resistance proportionally to the intensity of the shading of the negative and thereby controlled a graving tool working on another surface.

In all of these methods, it will be noted, photography takes the place of the former wood engraver's skill, while, however, utilising the same fundamental principles of a V-shaped translating device, in one form or another.

### Present-day Half-Tone.

A fifth method (the present half-tone process), came into vogue thanks to the scientific researches of Mr. F. E. Ives, in which, photographing through a screen, the subtle variations of light and shade of the object were translated into definitely related opaque and transparent portions of the negative, having variable areas of opaque and reciprocal transparent portions—an optical V. This negative, which photography, automatically and in a selective manner, depicted a "key," controls the action of a "chemical graver" on a metal surface so as to produce depressions of greater or less depth and larger or smaller area, is also analogous to the manual skill of the xylographer. What the mind was to the hand graver, the "screen" negative is to the chemical "graving" medium.

It will be quite apparent that all of the methods leading up to the existing half-tone process were of necessity based on the interpretative value of a V-shaped medium, mechanical, electrical or optical.

In the sixth method, of 1896 and 1903, a variable-surfaced photo-relief (or carbon print) made from an ordinary positive, without screen intervention, is placed upon a drum, and over this a pyralin, celluloid or other elastically resilient sheet is secured. A V-shaped cutter is firmly held on a traversing carriage adapted to move adjacent to the drum. When the cutter is adjusted to the proper depth, the drum is set into rotation, and the graver, directed by the gelatin relief under the pyralin, automatically cuts deeper and wider, shallower and narrower grooves with ridges standing between, varying in width inversely to the grooves. These ridges, similar to those of wood engravings, form the printing surface, which may be used direct or be electrotyped in the usual manner.

To S. H. Horgan belongs the honour of making the first half-tone reproduction for a daily newspaper, which was printed in the "Daily Graphic," of New York, March 4, 1880.

Meisenbach, of Berlin, Germany, did much research work in developing the law relating to the distance the screen should be placed from the sensitive plate. To early workers "Meisenbach's clichés" were synonymous with present-day half-tones.

### Rule of Thumb Half-Tone.

The half-tone method, using accurate Levy screens, has developed most skillful workers who produce marvellous results, and though the process is based on the most interesting scientific laws, unfortunately the average processman is concerned to a maximum degree with the purely practical aspect of the art and does not devote as much time to the theoretical and scientific phases of the method he utilises daily as he might do, greatly to his advantage.

It does not seem to be so much a lack of desire to know, as the strenuousness of application that precludes the entry of very little but the commercial into the treatment of subjects as they pass through his hands. Yet one must say, to be just, that the commercial requirements are very exacting as to results, and to this extent deserve credit for holding up the quality of the output.

On the other hand, it is possible for the process-worker to get away from a too-close adherence to an impersonal method to one that is replete with ever-recurring interest, because one may know definitely the laws of effects of the unit areas utilised, and from those judge intelligently as to the results that should come from any given effort.

The method in vogue, of judging results principally by the finished product, is all right so far as the end is concerned, but it is very unscientific. How could a mechanic produce results commensurate with any one's conceptions by weighing so much material, of certain definite proportions, etc., made up of various groups of similar-shaped pieces and machine the lot without knowing exactly the definite detail steps and dimensions of all the consecutive elements of his construction?

The process-worker, thanks to an inherent artistic ability, can and does proceed to splendid results without knowing definitely for himself the correlation of the various mathematical elements that have to do with his screen, distance, related to focal length of lens, shaped diaphragms, etc., that have to do with the optical part of his profession; or the equally important ones, of the relation of size of dot to unit area, the rate of side action to the resultant printing surface, the rapidity of acid action, the relation of depth to the contiguity of adjacent edges of the printing points—printing quality—and the percentage of broadening after the engraving reaches the press under the best printing conditions. These are all vitally

important to the processman. In the March number of the "Inland Printer" (B.J.P., April 27) were shown analyses of half-tones and tints made therefrom. These are all important, in order that one may judge intelligently as to the best procedure in "staging" his work.

However varied the phases of anything may be, a familiarity with fundamentals makes one a master of any situation that may arise. Such a familiarity broadens one's mental capabilities and develops resourcefulness.

The specimens shown have been described in detail, and it is thought will be of interest to the everyday worker, as well as persons devoted to the theoretical phases of the subject only. It has been the aim to present the various physical characteristics of half-tones in as popular a vein as possible so as to divorce the treatment from the purely theoretical, and to this end the deductions made and details given in the March issue were made from the engraver's proofs and the engravings themselves of the specimens shown.

N. S. AMSTUTZ.

### INDUSTRIAL ALCOHOL.

THE following is the portion of the Revenue Bill of Mr. Asquith now before the House of Commons which deals with the question of the industrial use of alcohol. The Bill carried out certain of the suggestions of the Royal Commission which last year published its report on the question, a summary of which report appeared in our columns for April 21, 1905, page 209:—

1. Provisions as to Spirits used in Art, Manufacture, etc.—(1) Where any spirits are used by an authorised methylator for making industrial methylated spirits, or are received by any person for use in any art or manufacture under Section 8 of the Finance Act, 1902, the like allowance shall be paid in respect of those spirits as is payable on the exportation of plain British spirits, and the Commissioners may by regulations prescribe the time and manner of the payment of the allowance and the proof to be given that the spirits have been or are to be used as aforesaid.

(2) No allowance shall be payable under this section on methylic alcohol, but foreign methylic alcohol may be received and used under Section 8 of the Finance Act, 1902, without payment of the difference of duty mentioned in that section.

(3) One-nineteenth shall, as respects methylated spirits other than mineralised methylated spirits, be substituted for one-ninth as the minimum proportion of the substance or combination of substances to be mixed with spirits under Sub-section 3 of Section 123 of the Spirits Act, 1880.

(4) Notwithstanding anything in Sub-section 2 of Section 8 of the Finance Act, 1902, an applicant under that section shall not be required to pay any expenses incurred in placing an officer in charge of his premises, except such expenses as, in the opinion of the Commissioners, are incurred for special attendances of the officer, made to meet the convenience of the applicant.

(5) Such quantity as the Commissioners may authorise by regulations in each case shall be substituted for fifty gallons in paragraph c of Section 126 of the Spirits Act, 1880, as the maximum quantity of methylated spirits that may be received or be in the possession of a retailer at any one time; and for one gallon in paragraphs e and f of that section as the maximum quantity of methylated spirit which a retailer may receive from another retailer at a time, and as the maximum quantity which a retailer may sell to or for the use of any one person at a time respectively.

2. Supplemental Amendments of the Spirits Act.—(1) Section 122 of the Spirits Act, 1880 (which forbids the supply of methylated spirits except to the persons mentioned in the section), shall be construed as if, as regards the supply of industrial methylated spirits, a retailer of methylated spirits was not a person excepted under that section.

(2) A retailer of methylated spirits shall not receive or have in his possession any methylated spirits except such as may be authorised by regulations, and if any such retailer contravenes this provision he shall, for each offence, incur a fine of fifty pounds, and the spirits in respect of which the offence is committed shall be forfeited.

(3) Every vessel in which an authorised methylator stores, keeps, or supplies industrial methylated spirits, or mineralised methylated spirits, must be labelled in such a manner as to show that the

methylated spirits are industrial or mineralised as the case may be, and if an authorised methylator fails to comply with this provision he shall, for each offence, incur a fine of fifty pounds, and the spirits with respect to which the offence is committed shall be forfeited.

(4) In addition to the account required to be kept by the proper officer under Sub-section 1 of Section 125 of the Spirits Act, 1880, an authorised methylator shall keep distinct accounts in the prescribed forms of any industrial methylated spirits and of any mineralised methylated spirits prepared or received by him and of the sale, use, and delivery thereof, and that section shall apply with reference to each of those accounts and the spirits to which the account relates as it applies with reference to the stock account therein mentioned and to methylated spirits generally.

(5) Section 130 of the Spirits Act, 1880, shall apply as if it were an offence under that section without the consent in writing of the Commissioners, or otherwise than in accordance with regulations, to purify or attempt to purify methylated spirits or methylic alcohol, or after methylated spirits of methylic alcohol have once been used, to recover or attempt to recover the spirit or alcohol by distillation or condensation, or in any other manner.

(6) Sub-section 2 of Section 130 of the Spirits Act, 1880, shall apply as respects any article specified in an order of the Commissioners as it applies with respect to sulphuric ether or chloroform.

### PHOTOGRAPHY AT THE BRITISH MUSEUM.

THE following letter from the Publishers' Association of Great Britain and Ireland appeared in the "Times" last week. We refer to the grounds of complaint under "Ex Cathedra."

"For many years the public have had facilities for photographing from the national collection at the British Museum without charge, and this privilege (if it may not even be regarded as a right) has been largely used by publishers, who find in the print room and library valuable material for the illustration of books.

"Certain reasonable restrictions have always been enforced, but the Trustees have suddenly (from May 1) imposed a charge of 2s. for each negative, or a time charge of 1s. per hour.

"Though in some cases this change may appear inconsiderable, there are others, involving a large number of photographs, in which the cost of publication will be materially increased; and in any case it appears to the council of our association that a body who contribute so much as the publishers of the United Kingdom to the library of the British Museum should not be subjected to this additional impost.

"It may not be generally known that the British Museum has a special advantage over the other four libraries which are by statute entitled to free copies of every publication, in that the Trustees may and do claim a copy of every book, printed on the best paper, and in the most complete form in which it is issued; the result being that, whenever a special edition printed on large or hand-made paper, or with extra illustrations, is issued, the publisher has to contribute gratuitously to the National Library a copy of a book which may be worth to him ten, fifteen, or even fifty guineas, instead of the less costly edition, which would in most cases answer the purpose of readers.

"It may also be noted that the process of copying valuable MSS. or portions of scarce books by photography has great advantages over older methods of copying, inasmuch as it saves wear and tear of the subject copied, and shortens the time during which the MSS. are monopolised. On these grounds we cannot but think that publishers, who form the majority of those interested in this matter, are entitled to complain of this tax upon their use of public property, and as direct representation to the authority has been without effect, we can only hope that you will give us your assistance in laying our case before the public."

A "CLUB" for professional photographers has been founded in New York. It is to be known as "The Photographers' Club of New York," and its objects are "the furtherance of business discussions, the interchange of ideas for mutual benefit, and social intercourse between the members." Mr. W. B. Stage has been elected president. The subscription will be one dollar per annum, and meetings at regular intervals are to be held at the studios of members.

## Photo-Mechanical Notes.

### Awards at the Brussels Process Exhibition.

At the international exhibition of photogravure held at Brussels at the beginning of this year the following awards were made to British exhibitors: Diplomas of Honour: The Art Photogravure Company, for photogravure; Carl Hentschel, Ltd., for half-tones in three and four colours; L.C.C. School of Photo-Engraving, Bolt Court; "The Process Photogram." Gold Medals: The Marshall Engraving Company, for half-tones in black and colour; Meisenbach Company, Ltd., for half-tone and photography; T. T. Waddington, for photogravure.

### Death of Mr. Ernest Fuchs.

The process world will be pained to hear of the sudden death on May 27 of Mr. Ernest Charles Fuchs, the proprietor and director of the Art Reproduction Company, Plough Court, Fetter Lane, E.C. Mr. Fuchs was in the habit of walking out early in the beautiful neighbourhood of Beckenham, in which he resided. He left home one morning as usual, and was last seen alive by a constable and game-keeper on the estate of a friend and neighbour of his. Twelve hours later his body was found by the side of a shallow lake in the grounds. At the inquest death was discovered to have been caused by the bursting of a blood-vessel in the brain, arising from tubercular meningitis of very long standing. Mr. Fuchs, who was only forty-three years of age, was a native of Breslau, where his eighty-three-year old father still survives him, but was a naturalised Englishman. His decease is very greatly deplored by many friends and by the staff of the Art Photogravure Company, who, on hearing the sad news, at once voted part of the funds accumulated for the firm's annual outing to provide a subscription to the German Hospital, in the name of Mr. Fuchs.

### Austrian Process Work at Earl's Court Exhibition.

So much excellent reproduction work emanating from the Austrian Empire, it is to be regretted that more process firms are not exhibitors at the Earl's Court Exhibition, which has lately opened. There are, however, the productions of a number of firms and institutions which will repay a visit to the grounds of the exhibition even if the countless other inducements in the shape of good music, novel sideshows, and crowds of good-looking people fail to persuade the merely technical person to journey to the spacious buildings of South Kensington. The Imperial Establishment of Graphic Arts in Vienna, of the photographic and photo-mechanical sections of which Dr. Eder is the principal, exhibits photographs by various processes, collotypes and examples of almost all the photo-mechanical methods. An exceptionally fine show is made by the well-known firm of Angerer and Goeschl, of Vienna, which city is represented also by the firm of Löwy. Prague sends post-cards in "process" by the firm of W. Schulze, and photo-engravings in monochrome and three-colour by the well-known house of Husnik and Hausler, represented in this country by Mr. F. C. Clarkson, of Colchester.

### PHOTO-MECHANICAL PATENTS.

Improvements in heliogravure printing have been patented by Edward Mertens, 46, Lincoln's Inn Fields, London. (No. 10,112.)

An improvement in photo-mechanical printing has also been patented by John William Ippers, 65, Chancery Lane, London. (No. 11,971.)

### FORTHCOMING EXHIBITIONS.

November 16 to 21: Southsea C.C.—Hon. Sec., F. S. Hoyte, "Lismore," Stafford Road, Southsea.

November 27 to 30: Hove C.C.—Hon. Sec., W. H. Bone, 32, Sackville Road, Hove.

December 11 to 15: Southampton C.C.—Hon. Sec., S. G. Kimber, "Oakdene," Highfield, Southampton.

October 17 to 20: Rotherham Photographic Society.—Sec., H. C. Hemmingway, Tooker Road, Rotherham.

1907.

February 12 to 23: Sheffield Photographic Society.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge.

## Patent News.

*Process patents—applications and specifications—are treated as "Photo Mechanical Notes."*

The following applications for patents were made between May 1 and 26:—

**LIGHT SCREENS.**—No. 11,789. Improvements for light-screens in cameras. Hermann Müller, 48, Avenue de Beauté, St. Maurice, Seine, France.

**DISHES.**—No. 11,813. Improvements in photographic dishes. Thomas Mintario Bailey Moore and George Moodie, 3, North Side, Clapham Common, London, S.W.

**TRIMMING PRINTS.**—No. 11,846. Improved device for facilitating the cutting or trimming of photographic prints. Frederick Colin Viscount Maitland, 11, Southampton Buildings, London, E.C.

**FILM-PACKS.**—No. 11,884. Improved daylight-loading photographic film packs. John Edward Thornton, Altrincham, Cheshire.

**CINEMATOGRAPHS.**—No. 11,940. Cinematographic apparatus. Stephen Drummond Chalmers and Clara Chalmers, 8, Quality Court, London, E.C.

**COLOUR PHOTOGRAPHY.**—No. 11,986. Improvements in dark-slides for colour photography. Albert Muller, 18, Southampton Buildings, London, E.C.

**FILM-PACKS.**—No. 12,003. Improvements in the design, construction, and manufacture of film-packs for daylight loading and their contents. John Edward Thornton, Altrincham, Cheshire.

**DARK-SLIDES.**—No. 12,003. Improvements in photographic dark-slides, change boxes, and cameras and films for use therein. John Edward Thornton, Altrincham, Cheshire.

**VIEW FINDERS.**—No. 12,069. Improvements in view finders for photographic cameras. Adolph Richard Lange, 55, Chancery Lane, London, E.C.

**CINEMATOGRAPHS.**—No. 12,072. Improvements in cinematographs. Casimir de Proszynski, 7, Southampton Buildings, London.

**DARK-SLIDES.**—No. 12,126. Improvements in dark-slides for photographic purposes. William Watson, 45, Chestnut Walk, Walthamstow, Essex.

**SCREENS FOR COLOUR PHOTOGRAPHY.**—No. 12,235. Adjustable compensating screen for use in photography and in colour photography. Charles Adrien Brasseur, 18, Southampton Buildings, London, E.C.

**CAMERAS.**—No. 12,254. Photographic cameras. Joseph Constance Jones, 55, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**COLOUR PHOTOGRAPHY.**—No. 20,662, 1905. The invention relates to a direct one-plate method of colour-photography, in which a banded filter is formed on a glass plate by a photographic process, a coating of sensitive emulsion being afterwards applied. To the surface of a glass plate is applied a film of, say, bichromated gelatine. A pattern is then applied, preferably in the form of a glass plate bearing on its face opaque bands, which are double the width of the bands to be produced upon the screen, and which are spaced apart a distance equal to the desired width of the proposed bands. An exposure to light is now made through the pattern plate, thereby rendering insoluble those portions of the sensitised film which are not covered by the opaque bands, the covered portions, however, not being acted upon by the light. The portions of its film which remain soluble are now washed away, leaving the face of the plate covered with bands of material used of the desired width and spaced apart double their width. The plate is now given a dye-bath—usually of green at this stage. The colour absorbed by the material forming the bands is now mordanted, and the plate is thoroughly washed to remove all traces of colour from its uncovered portions, and is then given a specially-prepared bath for the purpose of toughening and hardening the material carrying the dye and rendering it non-porous. For this purpose a bath is used containing about one pound of

tannic acid in a gallon of water. After carefully cleaning the plate there is now applied to the same surface a second film of the sensitised material. The opaque ruled screen is again applied, care being taken that its opaque portions entirely cover the coloured bands already formed, and as they are twice the width of these bands they will also cover one-half of the intervening plain portions of the surface. If desired, one of the edges of the opaque band may be brought exactly to coincide with one of the edges of each of the coloured bands, but this exactitude is not essential, providing no portion of the coloured bands is left uncovered. The operations already described of exposing to the light, washing, dyeing, mordanting, and toughening are now repeated, a dye of red colour being employed at this stage. The plate is now found to bear two sets of coloured bands, respectively green and red in colour, such bands together covering two-thirds of its face. These bands will appear in juxtaposed pairs or will all be spaced apart according as the pattern screen has or has not been applied to bring its opaque bands into register at one edge with one of the edges of the coloured bands first formed. The plate is now coated a third time with the sensitised material and given an exposure in such manner that the light reaches only those portions of the new film which lie between the coloured bands already formed. This exposure may be made through the reverse side of the glass, the coloured bands cutting off the light so that it does not reach the portions of the sensitised film which they carry, since the exposure will be of such short duration that the film will not be affected by the light passing through the coloured bands sufficiently to render any part of it insoluble. As an extra precaution, however, the very obvious expedient of employing a filter of the colour remaining to be added is available, and is, in fact, resorted to—i.e., the red and green bands being already on the plate, a blue filter will be used, which will eliminate from the light the red and green rays, leaving only the blue rays, and these, of course, will be effectually cut off by the red and green bands. Inasmuch, therefore, as only the red and green rays could possibly act upon the parts of the film lying on top of the red and green bands, and inasmuch as the filter cuts off these rays entirely, there can be no action on this part of the film. If the coloured bands already formed are arranged in juxtaposed pairs the opaque ruled pattern screen may be employed in making this third exposure, being so applied to the sensitised plate as to entirely cover the coloured bands which it bears. After this exposure the operations already described of washing out the portions of the film remaining soluble, dyeing, the blue dye being now used if in the two previous operations there have been employed, respectively, green and red, mordanting and toughening are repeated, and the screen is now ready for service. Such a screen is to be used in the taking of a picture in the usual manner, either by interposing it between the sensitised plate and the lens of a camera, or the sensitised material being applied directly to its colour-coated face and the exposure made through its back. John Hutchinson Powrie, 618, The Plaza, Chicago, Ill.

**POSITIVES DIRECT.**—No. 22,735, 1905. The invention consists of a sensitised photographic surface, consisting of a transparent support bearing a coating, which is, or can be, made relatively opaque when viewed by reflected light, which is also relatively transparent to transmitted light, and which is of a colour suitable to the finished picture. Barium sulphate suspended in gelatine or collodion is suitable for ordinary black and white prints. The transparent material coated with it has a further coat of sensitive emulsion: exposure in the camera being made through the transparent support and relatively transparent coating. The image, as produced in the camera, is a positive as regards the position of the object photographed, and the lights and shades of the image can be given a positive quality when viewed by reflected light by any of the methods usually practised. Thus, developed portions of the image may be removed with acids which will not affect the unaltered portions, and the latter can then be exposed to actinic light, and redeveloped after such second exposure; but it is preferred to remove the developed portions of the image, after the first exposure, by subjecting them to the action of an acid; for

instance, sulphuric or nitric acid, with or without an oxidising agent, such as permanganate of potash, and omitting the second exposure to light and the subsequent development, to change the unaltered portions of the film to a different colour or shade by a direct and almost instantaneous method. By thus omitting the second exposure, it is possible to dispense with the use of some uniform or artificial light, which would be inconvenient in many cases—for instance, in automatic photographic machines. To change the colour of the unreduced silver salt from white to black or brown, a bath of sulphide of soda, of potassium, or of ammonium is used. Barium sulphate is preferably used for the coating, because it can be incorporated in several ways with the medium which carries it, and because it is a practically inert substance. Instead, however, of mixing barium sulphate with the gelatine or collodion, one may use chloride of barium, for instance, which will not detract from the transparency of the film, the barium sulphate pigment being subsequently precipitated by the action of the sulphate generally present in the developing solutions employed, or being precipitated by special treatment with a sulphate. George Nicholas Piper, 1,210, Schofield Building, Cleveland, Ohio, U.S.A.

**CAMERAS.**—No. 23,387. The claims are (1) for a method of adjustment by which the movement of the shutter, forming part of the camera, is retarded by an adjustable bellows, thus varying the degree of exposure; and (2) for a special arrangement of mirror in a reflex camera fitted with the above type of shutter. Charles Howell and George Lloyd Moore, of the Midland Camera Company, Limited, Slaney Street, Birmingham.

**CONCAVE BACKGROUNDS.**—No. 8,248, 1906. The invention consists in the method of constructing a concave background, wherein the outer support for the concave surface is made as a single sheet, stretched or held to a suitable shape, so that in operation the outer sheet cannot come in contact with the inner one. Mariano Fortwing, 19, Boulevard Berthier, Paris.

**RECORDING APPARATUS.**—No. 20,579, 1905. The claim concerns photographic recording apparatus, with galvanometer, consisting of coils, oscillating system, and magnet, and is for arranging some of the parts of the galvanometer, and in particular the magnet, stationary (while the shifting of the middle position of the ray of light necessary for the production of the continuous curve lines is effected) by the turning motion of the other parts of the galvanometer. Siemens and Halske Aktiengesellschaft, 3, Askamscher Platz, Berlin.

**ELECTRICAL PRINTING MACHINES.**—No. 235, 1906. The claim relates to apparatus for successively exposing to the rays of electric lamps portions of a photographic film, and specifies the combination of a main driving electromotor and an auxiliary controlling electromotor, with a switch adapted, to be alternately operated by the motors in such a manner that electric current is alternately supplied to the circuit of the driving motor and to the circuit of the auxiliary motor and lamps. Otto Lienekampf, 9, Johannisallee, Leipzig-Reudnitz, Germany.

**JAPANESE Tariff Reform.**—In the revised tariff which Japan has recently adopted to meet war expenses the duties have been altered in a number of cases. The following are the amounts on 100 kin of the following photographic manufactures:—

	Yen.	Sen.
Albumen and sensitised paper .....	65	90
Bromide and platinum paper .....	112	0
All other kinds of photographic papers .....	89	40
Photographic dry plates .....	18	20
Photographic instruments .....	50	per cent.
Photographic films .....	40	per cent.
Lenses and other optical glasses .....	30	per cent.

**"Mixed Soda."**—At the Gosport Police-court on May 25 a firm of wholesale grocers was summoned for selling a mixture of Glauber's salt and carbonate of soda as "washing soda" or "soda." Evidence was given by analysts as to the composition of the mixture, but the defence was that a placard was displayed in the shop to the effect: "All soda, being composed of carbonate of soda and sulphate of soda, is sold at this establishment as mixed soda. A fine of £20 was inflicted, and defendants were ordered to pay ten guineas towards the costs of the prosecution.

## New Books.

"The Proceedings of the Optical Convention, 1905." London: Williams and Norgate. 10s. net.

As a year has elapsed since the opening of this convention, these proceedings are somewhat belated. Nevertheless, they are very welcome, for they form a most valuable and comprehensive volume that no one interested in optics can afford to be without. We may indeed fairly describe it as the most valuable contribution to optical literature that has been published for some considerable time. The book contains thirty lectures with reports of the consequent discussions, and is very fully illustrated. The following may be selected as likely to be of the greatest interest to photographers:—The inaugural address by the President, R. T. Glazebrook, D.Sc., F.R.S., is a most useful though brief history of optics, and is followed by a biographical chart of some optical workers, drawn up by Fred. J. Cheshire, F.R.M.S. Then there is an excellent paper by Mr. Conrad Beck on the "Equivalent Planes of Optical Instruments," which gives much interesting information not to be found in text-books. This is followed by a discussion on Aberrations, introduced by Dr. C. V. Drysdale and Mr. S. D. Chalmers, M.A. Later on we find the "Early History of Telephotography," by Gen. Waterhouse, and a paper on "Stereoscopic Vision," by Mr. C. W. S. Crawley. Mr. J. H. Blakesley, M.A., has a paper on "Lens Measurements," and Mr. A. J. Bull on "Trichromatic Photography."

Spectroscopes and spectroscopy receive much attention, as there are four important lectures on these matters. Mr. F. Twyman describes the Michelson Echelon Diffraction Grating and the Lummer Parallel Plate Spectroscope. Mr. Blakesley deals with constant deviation spectroscopes; Mr. Newall, F.R.S., with the spectroscope in astronomy, and Professor Schuster, F.R.S., gives a most valuable paper on the "Optics of the Spectroscope."

There are also two very useful papers on photometry. One on "Photometric Measurements," by Mr. A. C. Jolley, and one on the "Absorption Spectrophotometer," by Mr. J. R. Milne, B.Sc., F.R.S.E.

Among the papers of general interest we may especially note one on the "Polishing of Glass Surfaces," by Lord Rayleigh, O.M., and one on the "Nicol Prism and Its Modern Varieties," by Professor Sylvanus P. Thompson, F.R.S. We had the pleasure of hearing both these lectures, which were brilliant examples of what lectures should be.

The discussions that follow the majority of the lectures are a most valuable feature of the book. Some of the subjects were of a controversial nature, and it is not in all cases possible to agree with every statement of the author. The discussions serve to warn readers of the doubtful points, and preserve the book from the dogmatic character of the orthodox text-book. In fact, there is nothing of the text-book about this publication, which gives simply the ideas of practical scientists actively engaged in both the study and practice of optics. The exponents of pedantic theories and the compilers who simply republish other people's ideas have played no part in the production of this valuable book. We have only one criticism to make. At none of the lectures that we attended did we hear the smallest reference to Abbe's theory of pupils. There were many references to the Gauss theory, but we heard none to the Abbe theory, and have not found any on glancing through the book. This most important part of the theory of lenses seems to be neglected in a most unwarrantable fashion in this country.

"London from the Top of a Bus." Pictured in forty-seven photographs. By Henry Irving. London: Hodder and Stoughton. 1s. Living London of to-day is what Mr. Irving has set out to offer in this illustrated guide to the important thoroughfares of Central London, and the photographs speak for themselves. All of them, so we learn from the preface, have actually been made from the roof of an omnibus as the latter was making its usual journey, and there is no fault to find with most of them on account of the elevated standpoint which has been adopted. Indeed, it may be maintained that the Londoner sees the streets of the City and the West End more frequently from the top of the bus than from the pavement level. In some instances the height of the camera has defaced the foreground; but as a whole the snapshots are a remarkably successful series. It will be noticed that exposures made with the lens pointing in the direction of motion of the bus have given better

results than those in which the photographer has looked back to get his picture. To those visiting London with a camera the book is the most interesting and useful guide they can have in making the tour of the town. The total cost of the bus fares is 11d.

STILL another elementary manual on photography makes its appearance in a third number of the "Focus" series, "Photography Made Easy," by Qui Vive, issued by Marshall, Brookes, and Chalkley, price 6d. From the condensation of information in such a handbook much of the teaching is bound to impart a partial knowledge of many matters, but the new volume conveys a useful first impression of how to commence photography, and may be recommended for placing in the hands of beginners, particularly of those purchasing the cheaper kind of apparatus.

The official Guide to Hotels and Boarding Houses on the South-Western Railway Company's system has now reached the comfortable dimensions of 270 pages, and contains, in addition to the alphabetical tables of accommodation on the South Coast, the West of England, and the Channel Islands, many illustrated notes—in fact, one-third of the volume—on the attractions of the various resorts, a directory of golf links, and a great many particulars of the places mentioned, in the form of advertisements and otherwise. The volume, which includes a large map of the South-West of England and of the French Coast, may be obtained free from the booking offices of the company, or from the Traffic Manager, Waterloo Station, London, S.E.

A new edition of the popular manual, "Photography in a Nutshell," by Lieut.-General Hawkes, has been issued by Messrs. Iliffe. Its appearance brings the total number of copies of "The Nutshell" to 78,000.

MESSRS. BUTCHER have published a re-edition of their "Photography for Novices," parts of which have been revised and rewritten.

## New Materials.

"S. D." (simple development) Paper. Made by Marion and Co., Ltd., 22 and 23, Soho Square, London, W.

A further step towards the absolute simplification of photography is made in the introduction of this new printing paper, which contains its own developer minus the alkali necessary for its action. Simultaneously with its appearance on the market Messrs. Marion are bringing out a self-development plate which, like the paper, requires only immersion in a 10 per cent. solution of carbonate of soda to promote the action of the developing agents contained in the film. The plate we shall notice in a later issue. Meanwhile, we may say of the paper that it belongs to the "gaslight" order, requiring a fairly long exposure to gas or lamp light or a short exposure to weak daylight for the production of a developable image. An inch of magnesium ribbon burnt 12 in. distant from the negative is what the makers recommend as a fair average. There is little else to be said. The exposed paper is immersed in a solution made by dissolving 2 oz. of good washing soda in a pint of water, the print appears in some twenty seconds, is rinsed rapidly and transferred to an acid fixing bath such as is customarily used for gaslight printing papers, and after the usual washing it is finished. We have found the paper answer quite satisfactorily to this course of procedure, giving us prints which possessed all the pluck characteristic of the gaslight emulsion. Indeed, if we may say so, the contrast afforded by the paper is rather more than is usually obtained on gaslight papers, probably with intent on the part of the makers, since the users of such a simplified process may be expected to belong to the class which produces negatives deficient in good printing quality. There should be no cause for complaint that "S. D." does not give them the pluck which they observe in prints from negatives of greater contrasts.

From the rapidity with which a self-developing paper has followed on the heels of a commercial plate of the same description, it would seem as though we were in for an era of automatism in development papers and plates, just as the self-toning method has risen to relieve the printer in P.O.P. of the necessity of compounding toning baths. At present the enhanced price of these labour-saving materials may deter many from employing them, and it will be interesting to see whether the future will bring any substantial

ctions in this respect. Messrs. Marion, however, are to be gratulated on being first in the field with a self-developing paper, their product should attract a good deal of interest both from those who use and sell photographic materials. The prices of the "D." paper are based on ninepence for one dozen pieces of quarter-plate size.

Rotograph" Satin (bromide emulsion). Made by the Rotary Photographic Company, Ltd., 12, New Union Street, Moorfields, London, E.C.

In this new introduction the Rotary Company have to offer a sensitive material which is manipulated in exactly the same way as matte paper, but which affords prints with the characteristic texture and sheen of satin. We anticipated some trouble in the gelatin film leaving its support, but though we took no precautions as regards temperature, etc., we obtained not a single sign of frilling or loosening of the gelatine coating. The prepared satin is fairly flat, and is handled in the developing solution and in the fixing bath precisely as a paper print. We can well believe that for many of the decorative purposes of photography it will be found most useful, and will supplant the home sensitising of silk or satin which is occasionally practised. The effective results obtainable when these materials are the support of the sensitive salts have been demonstrated in the case of platinotype and other processes, but it should be a satisfaction to many to find the Rotary Company giving their attention to the manufacture of a bromide fabric. The texture of the finished print is one which will recommend it to photographers who aim at the so-called "broad" effect, and it loses nothing by a slight sheen which distinguishes the prints from those made on an ordinary sensitised cloth. The prices of the satin are fixed exactly double those of the Rotograph bromide papers, viz., 1s. per packet of twelve quarter-plate pieces, and other sizes in proportion.

Beryl-Caramel. Made by Lichtenstein and Co., Silvertown, London, E.

Messrs. Lichtenstein, the original makers of caramel in this country, have now introduced a patented modification of that material specially with a view to the improvement of its properties as a backing for other purposes. Of caramel as a backing it is very unnecessary to indulge in commendations. Of those who appreciate the advantages of backing—a class which includes the vast technical photographers—probably the large majority employ caramel as the backing substance, and their practice is based on the fact that no other material possesses so many of the properties which go to make a perfectly efficient backing. "Crystal caramel," hitherto supplied by Messrs. Lichtenstein permitted the manufacture of a backing mixture excellent in every way—drying quickly to a hard, non-brittle film of the proper optical qualities, and being soluble to a clear solution in water. The new preparation is generally similar, but is more highly absorptive, and is possessed of more rapid drying properties. Those who desire may modify the character of a backing by addition of a little spirit or glycerine. It is doubtful if they will improve on the beryl-caramel as purchased. The latter consists of a dark brown, thick fluid, sold so in the solid form, which, when applied with a brush to the backs of plates, dries in a few minutes at the ordinary temperature, or more quickly in a current of slightly warmed air. A simple plan of the makers to obtain rapid drying is to place a plate of aluminium between the backed surfaces of the dry plates, using an ordinary metal drying-rack for the purpose. The space between the warm metal and the coated glass is traversed by an upward current of air, which reduces the time of drying of the plates to about five minutes.

An alternative plan of applying the backing if quick drying is desired is to pour on the middle of a 5 by 4 plate as much of the beryl-caramel as will go on a shilling piece, to pour some proof spirit round it and mix and spread with a flat camel-hair brush. This is allowed to dry flat for a while, and afterwards finished vertically.

Another aid in the use of the backing consists in passing the palm of the hand over the coating before packing away. The slight surface of grease imparted by the hand will help to prevent any risk of the paper sticking to it.

A form of beryl-caramel is made specially for colour-sensitive plates, and gives a coating resembling Indian ink in its blackness.

In our experience the backing has shown no tendency to crack or flake off under working conditions. Films of the caramel exposed to light do exhibit signs of fritter, but the action of the light on the strongly absorptive compound is probably the cause of this difference in the light and dark.

The complete solubility of the coating in water should be one of its most appreciated qualities. It is not necessary to remove the caramel before development, though it is convenient and easy to do so. But in the developer it has no evil effects, dissolving freely as development proceeds.

We need not apologise for the length to which our notes on the new compound have run, for the use of a proper backing should be recognised even more widely than it is as a most valuable aid to good photography. Commercial backed plates, by relieving photographers of the trouble of backing, have assisted in this respect, but the scanty coating of backing often to be found on them is not sufficient to show the full benefits of backing, and falls short of practical requirements in severe cases. We understand that the new backing is now applied to several commercial plates—to their advantage, we should suppose, if the coating is a reasonably liberal one. For particulars of the prices at which the beryl-caramel is supplied in collapsible tubes and in tins of 14 lb., 28 lb., and 112 lb., the makers should be addressed.

"Tono," a ready-made combined bath, has been submitted to us by its makers, the Tono Company, 12, Ardwick Street, Burnley. The stock solution supplied, when diluted according to the directions, with twice its bulk of water, forms, we find, a toning and fixing bath which gives excellent brown and purple-brown tones in a few minutes. In this respect it quite bears out the claims of the makers, by whom also stress is laid on the permanence of the results. The latter is a point on which, for obvious reasons, we cannot pronounce any judgment, though the bath appears to us to resemble others of the combined type from which perfectly satisfactory results can be obtained so long as it is not overworked. In this connection we are glad to see that the Tono Company give precise instruction as to the number of prints which should be toned in it, the 1s. 6d. size being directed for the toning of 100 postcards. The preparation, we believe, will be found a reliable and efficient one.

In reference to our review of the "Tricol" plate, the Gem Dry Plate Company writes pointing out that the plate is more especially made for three-colour work. The firm proceeds:—"We certainly recommend a screen, although the plate will give a marked improvement without one, and we supply the necessary filter to give a perfect result with a minimum exposure. The ratio of yellow to blue sensitiveness is, of course, of little interest in considering this plate, as it is its red and green sensitiveness which are so very high, and which enable exposures to be given in the ratio of 1:1:2 for the blue, green and red filters respectively."

A SERIES of four postcard border-negatives reaches us from the Birmingham Photographic Company, Stechford, near Birmingham. The quaint, decorative designs form an agreeable surrounding to quarter-plate and smaller photographs. The price of the set is 4d.

ADDRESS WANTED.—Mr. W. Tylar, of Birmingham, asks us to notify the receipt of an order from a customer of his, Mr. John Wood, who writes from Teneriffe, but omits an address.

THE collection of photographic portraits by R. Dührkoop, brought together by the THE BRITISH JOURNAL OF PHOTOGRAPHY, and exhibited at Wellington Street for six weeks will be shown in a number of provincial centres during the next twelve months either in the regular exhibitions of societies or as separate shows arranged by local photographic associations. The societies who are thus taking upon themselves the duties of introducing Herr Dührkoop's work to the public are as follow:—Leeds Photographic Society, Southampton Camera Club, Southsea Photographic Society, Hove Camera Club, the photographic societies of Ulster, Coventry, Rotherham, Sheffield, Norwich and District, and Leicester, and the Photographic Society of Ireland.

A SCHOOL of "one-man" photography has been established in New York at 32, Union Square, by Mr. Milton Waide, who has long identified himself with this aspect of professional photography.

## Commercial & Legal Intelligence.

**A CANVASSING Theft.**—Last week, at the Bristol Police Court, Ernest Hill, stated to be an itinerant photographer, living at 28, Sevier Street, Ashley Vale, was charged with stealing two rings belonging to servants employed in Duchess Road, Clifton, whom he had photographed. The complainants said that after defendant had gone they missed their rings. Defendant alleged that he had taken tea with the girls, and they were party to the placing of their rings on his fingers. Suddenly the door bell rang and he was hurried out because the master was coming. Complainants denied these statements, except that relating to the appearance of the master. Prisoner was sentenced to a month's imprisonment for each offence.

At the London Bankruptcy Court, on May 25, H. W. Puetz, late of 6, Savage Gardens, E.C., merchant in chemicals, trading under the style of Hy. Wm. Puetz, appeared before Mr. Registrar Brougham for public examination upon accounts showing unsecured liabilities £1,099 1s. 10d., and assets £50 15s. In examination by Mr. Walter Boyle, assistant receiver, the debtor stated that he came to England from Berlin in 1896 and started as agent for a firm at the above address. He afterwards discontinued the agency, and in 1899 started importing photographic chemicals and plates. In October, 1905, the business was stopped owing to the largest and petitioning creditor having declined to supply him with goods, and proceedings being taken against him on his acceptances for goods supplied. His failure was also due to loss on debentures in a limited company in which he had put certain moneys. The examination was concluded.

**EASTMAN Kodak Company, of New Jersey.**—The usual quarterly dividends of  $\frac{1}{4}$  per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of  $\frac{2}{4}$  per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock, have been declared by the Eastman Kodak Company, of New Jersey, payable on July 2, 1906, to stockholders of record at the close of business on May 31, 1906.

**THE "Tixit" Trade Mark.**—On Thursday, May 31, the case of Henry v. Berry and Roberts, Limited, came before Mr. Justice Bucknill in chambers. The action was brought by Mr. William Ethelbert Henry, trading as the Vanguard Manufacturing Company, Maidenhead, against the defendant company (who are wholesale agents carrying on business in St. Bride Street, E.C.) for an injunction restraining the defendants from infringing the plaintiff's trade mark "Tixit" and for damages. After hearing Mr. Lowenthal, instructed by Mr. T. W. Stuchbery, solicitor, Maidenhead, for the plaintiff, his lordship granted an injunction restraining the defendant company, their agents, and servants, and every one of them from selling or exposing for sale any jar, bottle, or other receptacle containing adhesive paste and marked with the plaintiff's trade mark "Tixit," or from otherwise infringing or wrongfully using the plaintiff's trade mark, to be made perpetual. Defendants to deliver up to the plaintiff for destruction all goods in their possession bearing the plaintiff's trade mark, and to pay the taxed costs of the action. The application to be treated as the trial of the action, and judgment to be signed accordingly. The defendants were further ordered to pay damages to be assessed by the Court, unless otherwise agreed.

### NEW COMPANIES.

**FUNLAND, Limited.**—Registered May 23. Capital £100, in £1 shares. Objects: to carry on the business of exhibitors of stereoscopic views by means of automatic machines and otherwise, showmen, photographers, art publishers, etc. No initial public issue. Registered without articles of association. Registered office, 170, Edgware Road, W.

**ESME COLLINGS (Home), Limited.**—Registered May 24. Capital £500, in £1 shares. Objects: to acquire the business carried on at 120, Western Road, Hove, as Esme Collings, and to carry on the business of photographers, dealers in photographs and photographic accessories, etc. No initial public issue. Registered office, 41, Poland Street, Oxford Street, W.

## Correspondence.

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE STATE OF WINCHESTER CATHEDRAL.

To the Editors.

Gentlemen,—I am glad to be corrected by so incontrovertible photographic authority as Mr. S. G. Kimber, who doubtless knows Winchester Cathedral exceedingly well. My only object in writing the B.J. was to save members of the association from possible disappointment at finding on their arrival many of its most interesting features not available for the camera.

If I have "laboured" my statement so as to avoid disappointment in one single instance my letter will have achieved its object.—I am, gentlemen, etc.,

Winchester, June 2, 1906.

W. T. GREEN.

To the Editors.

Gentlemen,—I read with interest the correspondence of the past two weeks, but do not understand why Mr. S. G. Kimber should endeavour to represent "the best portions from a photographic point of view," as being available for photography. Apparently, opinions differ as to "the best portions." It is true the Great Screen, a magnificent work of art, is still free from the ravages of time from which other portions of the cathedral have suffered, but the most picturesque parts, including the exquisite chantries and chapels, are closed to the public. Mr. Kimber is perhaps accurate in his statement that only one-sixth of the building is contained in these parts. But he does not state that the remainder is taken up almost exclusively by the great nave and choir.

Your correspondent, Mr. W. T. Green, might have gone much further in his statements, as the beautiful north transept is at the present time used as a place to store chairs in, thus baffling the photographer in any attempt to secure a good picture of this rich Norman architecture. Practically there is only the nave, choir and screen available to the photographer unless he cares to turn his attention to the numerous monuments which adorn the side of the aisles.

The exterior offers even less scope for the camera. The north and south fronts are the only portions not disfigured by the builders. It is not necessary to point out to photographers the best time of day to photograph the north side of a building, and the south side of the cathedral can only be photographed in parts owing to the dense foliage of the immense lime trees which are so close to the building, as to render it impossible to get a general view of this side.

From the number of postcard views Mr. Kimber supplies to the local shop-keepers, one must conclude he has a very intimate knowledge of the cathedral, but he cannot have paid it a very recent visit, or he would be assured Mr. Green's statements are by no means overdrawn.

As the latter's account is drawn chiefly from the illustrated appeal for funds published by the Dean and Chapter, I fail to see why he should be accused of writing "a laboured account," which might have the effect of keeping intended visitors away.

On the contrary, Mr. Green has done much towards bringing the cathedral into prominent notice, and his photographic knowledge of the edifice is much more extensive than that of any other photographer. Both writers, however, seemed to have missed the fact that in addition to its splendid Cathedral Church, Winchester abounds in buildings of quaint and architectural interest, which the most enthusiastic photographer would find it difficult to include in a day's work. I am only too anxious that the members of the Convention should pay this beautiful city a visit, but I must point out here, as I have previously done in correspondence with the President of the Convention, that visitors who come with the sole purpose of securing a series of views of the cathedral, will be unfortunately disappointed.

—Yours truly,

33, Southgate Street, Winchester.

June 2, 1906.

ALBERT GANDY.

## METRIC MEASURES.

To the Editors.

Gentlemen,—With reference to your note on my letter of May 23, I am obliged if you would permit me to point out that by the 18 Germinal An. III., the doubles and halves of all measures prescribed, which, of course, includes those of the Decametre. Things prevented the law being generally enforced till the 4th of July, 1837, which was obligatory from January 1, 1840. June 16 and July 17, 1839, the manner in which all recognised measures and measures were to be made was regulated by Ordinances regulate the manner in which chains of a decametre and double tre were to be made among other measures. This was not true, as you represent, an afterthought, but just as old as the rest system. As to the chain of twenty-five metres I have no information, but will make enquiry.

peristence in the use of old names for new units may occur likely enough, but since the sale of unstamped weights, etc., is illegal, and those which may be stamped are laid down by law, it is difficult to conceive that it can be of any serious importance, as it may suit some persons to represent it as such.—I am, gentlemen, your faithfully,  
J. F. TENNANT.  
Clifton Gardens, Maida Hill, W.  
June 1, 1906.

correspondent will probably find no official warranty for the chain, which was no doubt only introduced for convenience, as the 100ft. and 50ft. chains have been. The personal conception of the user is more potent in these matters than any Act of Parliament. Twenty-five metre chains are stocked and listed by the Survey of the Instruments, which is pretty good proof that they are in use. The confusion to which we referred is not due to the use of names for new units, but to the retention of old units. The foreign weights and measures "now in use," published in the 9th edition of the Encyclopædia Britannica, shows that a surprising number of the old units still survive in metric countries such as Portugal and Belgium. Another cause of trouble is the inability of the metric system to certain trades, and it does not seem that any satisfactory method of applying it to the measure of yarns has yet been evolved. It does not follow that a system admirably adapted to scientific work should be equally fitted to commerce and trades, and in our note we only suggested what appeared to be the most probable basis for the objections to the metric system which were reported to have been made by representatives of metric countries. It should be remembered that commercial interests are of the first importance in considering the use of weights and measures, and that they must have the final word in the matter in these democratic days. As the adoption of the metric system is not at present a matter of practical importance, it is not worth while pressing the subject further.—Eds., June 1, 1906.

## THE COLOUR OF URANIUM TONED IMAGES.

To the Editors.

Gentlemen,—Mr. Welborne Piper's letter on p. 417 of the 25th June deals in its last paragraph with this subject, and he says that it attributes the brown colour to deficiency of ferricyanide. This is wrong in theory, for Atterberg pointed out the formation of two tones, and this is also confirmed by L. P. Clerc (B.J., April 20, 1900, p. 10), who states that the red ferrocyanide of uranium has the formula  $K_2 UO_2 Fe(CN)_6 \cdot 2 H_2O$ , and to make this, eight molecules of potassium ferricyanide  $K_3 Fe(CN)_6$ , and fifteen molecules of uranic acetate, that is, 5,264 parts of the first with 6,390 of the second, are required.

A brown ferrocyanide has the formula  $K_2 UO_2 \cdot 2 [Fe(CN)_6]$  and eight molecules of potassium ferricyanide, and eighteen molecules of uranic acetate are required, or 5,264 parts of the first with 7,668 parts of the latter.

Mr. Piper advises, however, exaggerating the proportions of the uranic salt required, and that of the ferricyanide if the red is required, and gives the following table:—

Tone.	Sol. A.	Sol. B.
Deep brown.....	50 cc. ....	100 cc.
Reddish-brown .....	50 cc. ....	70 cc.
Violet red .....	50 cc. ....	55 cc.

Solution A being a 1 per cent. solution of ferricyanide, and B a 1 per cent. solution of uranic acetate, both containing 10 per cent. of glacial acetic acid.

Not having any uranic acetate I took equivalent molecules of the nitrate, using the theoretical proportions laid down by Clerc, not using the excess as he advises. I enclose herewith a couple of lantern-slides treated with these solutions. A is that toned with the formula to give red tones, that is, with less uranic. B was treated with the solution containing the greater proportion of uranic. Each slide was allowed to remain in the solution for sixty minutes to ensure as far as possible completeness of action, then washed in water acidulated with glacial acetic acid, with six changes after ten minutes' soaking in each case: the idea in this being to eliminate any possible doubt as to the colour of the deposit by any staining of the gelatine.

There is no question in my mind that A is distinctly redder, and B a clear brown.

There is, however, one point which I did notice: when a second slide was immersed in the solution containing excess of uranic the tone was a brilliant red. Now might not this be due to the greater proportion of the uranic being deposited on the first slide, and is it not a possible explanation of some of the discordant results which Mr. Welborne Piper has obtained? This last slide I have labelled C.

With regard to the particular intensifier to which Mr. Welborne Piper alludes, that gave him a clear red stain, this was, if he and I allude to the same solution, the subject of a patent, and contained a mixture of uranic nitrate, ferricyanide, ammonium sulphocyanide, and an acid. I enclose also a slide D toned in such a solution. This was made by adding some sulphocyanide to part of the solution containing excess of ferricyanide in which slide A was toned; the result is a perfectly clear red stain.

Personally I doubt whether, in the face of the bad reputation which uranic toned images have, the subject is worth pursuing further; though on the other hand in the paper by Clerc, already alluded to, he states that some uranic-toned prints had hung in his laboratory for years, exposed to light and all the fumes of a laboratory, without showing deterioration.

In the face of your editorial comment to my previous notes, it is hardly worth while replying to Mr. Baker's pseudo-scientific letter.—Yours faithfully,  
E. J. WALL.

Sidcup, June 4.

[We should call the first transparency a bright brownish-red; the second a very good brown. The stain-like character of the deposit of the slide toned in the solution containing sulphocyanide is very marked, and there is a curious whitening of the very deepest shadows which would suggest that the process had not reached a conclusion in these portions.—Eds., B.J.P.]

## THE BLEACH-OUT PROCESS OF COLOUR-PHOTOGRAPHY.

To the Editors.

Gentlemen,—As my name has recently been frequently associated in the British Press with that of Mr. Jan Sczezeapanik, will you please allow me to make public the fact that I am now in no way associated with Sczezeapanik's bleach-out system of photography. After giving that system (which consists in coating the coloured emulsions in isolated layers) a thorough trial, I was forced to come to the conclusion that the system, in addition to the technical difficulties and greater expense involved, gave much less satisfactory results than those obtainable with a single layer of mixed colours.

All the recent examples of the bleach-out process which I have exhibited were produced by an improved one-film process worked out and protected by several patent applications by Dr. W. Merckens and myself, and which we wish to be referred to as the Smith-Merckens bleach-out process. The method is being rapidly improved, and we are sending to the International Exhibition at Milan, and to the "Allgemeine" Photographic Exhibition in Berlin, some fifty framed copies made mostly from delicately colour-toned originals, which show that even fine shades of colouring can be well rendered by our new process.

Our English agent is Mr. Oliver Dawson, No. 254a, High Holborn.—Yours faithfully,  
J. H. SMITH, Ph.D., F.I.C., Assoc. R.C.S.E.  
Zurich, Switzerland.

June 1, 1906.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
9 .....	Hull Photographic Society	Outing to Brock o' Dale Woods.
9 .....	Aberdeen Photo Art Club	Outing to Putniedden (Woodlands).
9 .....	Halifax Camera Club	Outing to Southdown.
9 .....	Bristol Photographic Club	Outing to Almondsbury.
9 .....	Chelsea and District Photo. Soc.	Outing to Waltham Abbey.
9 .....	Hackney Photographic Society	Outing to Theydon Bois.
9 .....	Redhill and District Cam. Club	Outing to River Thames.
12 .....	Bristol Photographic Club	Club Meeting at Headquarters.
12 .....	Royal Photographic Soc.	Ordinary Meeting. "The Picturesque in Landscape." Horace Mammery.
12 .....	Hackney Photographic Society	Paper by S. W. Morrison.
13 .....	North Middlesex Photo. Soc.	"The Selection of a Printing Process."
13 .....	Leeds Camera Club	Mr. H. W. Bennett.
13 .....	South Essex Camera Club	Excursion to Meanwood and Adel.
14 .....	Blackburn Camera Club	"Retouching and Working up Prints."
14 .....	Hackney Photographic Society	Mrs. Welford.
14 .....		Outing to Whalley Abbey.
14 .....		Outing to Oxted.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

**PHOTOGRAPHING MACHINERY.**—I have to take photographs of machine fittings (composed of brass and iron) for catalogue purposes. My workshop is only lit by a row of skylights; the walls are all white-washed brick. Will you kindly tell me how to proceed to obtain good prints without shutting out any light from the shop? The general size of the mechanism is about 3ft. square. I use a half-plate outfit. What colour background would be suitable?—A. B.

As the machines are so small you will no doubt be able to get them placed at any part of the shop where the light is most suitable. Failing that, if there is only direct top light over the machinery this may be softened by placing a light wooden frame covered with tissue paper some distance above machines. The shadows may be softened by putting sheets of white paper, or cardboard, so as to reflect the light upward. Usually with photographs of machinery, for catalogues, the backgrounds are blocked out in the negatives so that they print white. If you coat the machinery with the flattening colour, formula for which is

given on page 987 of the Almanac, it will simplify the greatly.

**TONING ALBUMEN PAPER.**—My recent enquiry replied to in journal of May 4, referred to the developer (or toning) mentioned in the "B.J. Almanac," 1906, p. 970. I therefore be glad if you would in your next issue favour me "a suitable bath to give cold (bluer) tones for albumen paper." SAMOHT.

Your query was answered in our issue of May 18. The following is a good bath for cold tones, but if you require bluish tone you had better use gelatine P.O.P., toning in a pho-cyanide bath:—Soda carbonate, 4 grs.; water, 8 to 10 gold chloride, 1 gr.; or

Boiling water, 8 ozs.; gold chloride, 1 gr.; chalk or whiting, 30 grs.; saturated solution of chloride of lime, 2 minims.

**COLOURING PHOTOGRAPHS.**—Would you kindly let me know what your opinion is, the best book on photographic colouring for specially miniature painting; the price, and where it may be had? Madder Brown.

No very recent work on the subject has been published. Son's book on the "The Art of Retouching Negatives and Colouring Photographs" is a useful work. Its price is two shillings. The book may be had through any of the dealers. "The Principles and Practice of Harmonious Colouring" is also a good book. Price, one shilling. It is published by Newman, 24, Soho Square, but we are not quite sure it is still in print.

**THE P.P.A.**—(1) To become a member of the Professional Photographers' Association must one earn their living entirely by photography? (2) What is the subscriptions, etc., to become a member? (3) Where can membership forms be obtained? Can the letters, M.P.P.A., be used on business cards, etc., in place of the full wording?—J. A.

You can obtain answers to all your questions by writing to the honorary secretary, 51, Baker Street, London, W., for the rules of the association.

**W. E. (Paisworth).**—We cannot say. Possibly if you apply to the Secretary of the Zoological Society, 3, Hanover Square, W., will be able to give you the information.

The exhibition of the photographs by A. Dührkoop, opened at Eberle Street Rooms of the Liverpool Amateur Photographic Association last Monday, and will remain available for free inspection by the public until June 16. It is to be hoped that our readers in the Liverpool district will take this opportunity of seeing a remarkably fine collection of work. The exhibition is open daily from 6, Saturdays 10 to 4. We may add that a series of one-day shows has been planned by the Liverpool Association as follows:

	Open.	Close.
Dr. C. Thurstan Holland, F.R.P.S.	June 20	July 2
C. F. Stuart	July 7	July 2
Joseph Appleby	July 23	Aug.
Dr. John W. Ellis, F.E.S., John Smith, J. H. Canevali, F. K. Glazebrook...	Aug. 11	Aug. 2
C. F. Inston, F.R.P.S.	Sept. 1	Sept. 1

The relief fund for the photographers in San Francisco amounts to 4,047 dollars.

**NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

supplement of one of the flower studies by Mr. Henry Stevens is sent with this issue. A notice of the present exhibition of Stevens's photographs appears on page 475.

neglected cause of deterioration of developers is the mixture of nitrite and carbonate in one solution. Many published formulæ omit the salts to be dissolved together, whence comes, in many cases, the staining qualities of the developers. (P. 462.)

Mr. A. Lockett shows that personal errors in using the Watkins system of factor development are likely to be slight, provided the "dark-room" is liberally lighted. (P. 464.)

the photographic section of the Congress of Applied Chemistry, in Rome, Herr Valenta brought forward a bromide emulsion for printing out; Professor W. N. Hartley spoke on the application of photography to chemistry; Herr Hans Schmidt read a paper on three-colour photography, and Dr. Voitech contributed a note on the effect of light on asphalt. (P. 465.)

methods of enlarging by arc light are mentioned on page 463.

a convenient device in hanging backgrounds is illustrated on page 471.

a business-bringing circular of an American photographer of New York is given on page 471.

a patent specification of the Dischner method of producing portraits in the studio with natural backgrounds has been published. Accessories for roll-films and a printing frame for paper in length are mentioned in other patents of the week. (P. 472.)

the question of sensitometric methods and processes of uranium printing are discussed by correspondents. (P. 477.)

a lively discussion of the genuineness of spirit photography is now being conducted in the *Daily Express*. (P. 471.)

## EX CATHEDRA.

### A Dis- tinction Without a Difference.

In the words of a well-known humorous song, " 'Tis hard to know where nature ends and art begins." Particularly hard it must be to those of our friends whose names we often recognise in the prize lists of "The Studio" competitions, after a pseudonym has veiled the authorship of the print when it first graced the magazine. Amongst the conditions attaching to this perennial tourney of photographs, our artistic contemporary makes the following suggestions gratuitously: "The technical merits of the photograph will not be so much considered as its correctness in relations of tone—in maintaining a proper balance of light and shade; in avoiding exaggerated contrasts, and in rightly expressing subtleties of tone gradations." It appears to us that if "The Studio" had insisted upon perfect technical photography, instead of putting a premium upon the temperamental vagaries of the so-called "artistic" worker, these four desiderata could have been secured at one sweep. If they are not technical matters (scorned of "The Studio"), what in the name of photography are they? To ask for them and decline technical merit is tantamount to asking for a swing, and refusing the principles of the pendulum. Regarding the question of truth of tone and subtleties of gradation, it is constantly manifested to us that those works of the camera which appeal most in the eloquence of beauty are precisely those wherein correctness of exposure has been wedded to correctness and simplicity of subsequent processes. Gum prints and others admitting of "alterations and repairs" may turn out to be beautiful things in some respects; but in the matter of tone values and delicate gradations, we find them usually wanting.

### Picture Postcards.

We have more than once commented on the fact that country photographers do not turn the picture postcard business to the account they might do if they were a little more enterprising. In many cases they take a series of pictures of the places and surrounding neighbourhood, publish them, and let their activities end here. The pictures become out of date, and the sale falls off, because people do not care to keep on sending the same pictures to their friends. Even if the same views were occasionally retaken from a slightly different point of sight, or under different conditions of lighting, or with the trees in a different state of foliage, they would appear as new pictures, although taken and published by the same photographer. Views taken for one of the large publishing houses for publication command a ready sale simply because they are new and the last taken, and not because they are any better than those issued by the local man. Indeed, the local man, being always on the spot, has a far better

opportunity of taking the pictures under the most favourable conditions as to lighting than the one who only visits the neighbourhood for a day or so and has to take the views just as he can, be the lighting what it may. If many local photographers would continually be issuing fresh pictures, taken under different aspects from the older ones, they would find it to their advantage, as it is always the latest taken that sells best, and the cost of taking the negatives, to one residing in the locality, is but a trivial matter.

\* \* \*

### Post-mortem Photography.

Coroners in this country have often to comment on the way that photographs are taken of deceased persons, and the little use they frequently are as a means of identification. Attention has also been drawn of late to the better way in which this work is done abroad, where the corpse is arranged so as to show the body as much as possible as it appeared in life. A reproduction in the "People" of this week of a photograph of the miscreant Morales, taken after death, shows how our system of post-mortem photography may often be improved upon. The photograph represents the corpse in a standing position, the body held up by two men, and well lighted, so as to show a good likeness and a recognisable portrait of the man. The two men supporting the body are also well portrayed. Of course, we cannot say if this is an authentic photograph or not, though we have no reason to doubt its genuineness. Still, it is easy to see how a spurious one might be produced. Be this as it may, the photograph serves to show how in many instances our system of photographing corpses as a means of identification may be remodelled. Had this photograph been taken with the corpse lying flat on a slab, as is the general way here, the result would have been widely different as a means of recognition.

\* \* \*

### Individuality in Mounting.

We have recently seen quite a number of professional portraits mounted on toned papers in the multiple method, the effect in most cases being good. There is no doubt that where the class of business done warrants any attempt at individuality of treatment, this style of mounting pays for itself. We say "pays for itself" advisedly, for until one comes to select the tints of papers and to decide the width of margin to be shown of each tint, they can have little idea of the amount of time needed for the securing of a good effect. If, however, the full dozen prints are mounted alike, the time per print does not work out excessively high, and to persons of cultivated taste the effect is undoubtedly superior to that produced by many of the stock commercial boards. Those of our readers who were able to see the recent exhibition of Herr Dührkoop's work at the B.J. offices would notice the admirable way in which the fine qualities of the prints were enhanced by suitable mounting. Mere eccentricity should be guarded against, and the worker should have a reason for anything he has done, and be able to state it if any question arises. Decentralisation of the print is sometimes effective, but unless the balance is improved it is better not to so mount the picture. Moderation, the adoption of quiet, refined effects, will be found to answer best in the long run, while occasionally something more forcible may be shown.

### Hanging of Backgrounds.

The disposing of backgrounds so that they are always available when wanted, never in the way when not of use, and preserved from damage at all times, is one of the difficult problems of studio management. Mr. A. W. Judd, of

Chattanooga, describes in an American journal his method of dealing with the problem, and the illustration on another page shows the arrangement of his studio. Mr. Judd says: "For over forty years I have been taxing my patience with the feet and castors of the backgrounds. They are so unsightly, noisy; I require so much room and time to arrange them. I took some wire about one-eighth inch with curved ends, and hung from the ceiling in screw eyes. Into these hooks I put ordinary curtain poles with the background tacked to them, another pole being tacked to the bottom. Wires were attached to the (smaller) heads of the grounds so as to attach them to any pole. In this way I changed my backgrounds with ease and rapidity, without noise and disturbing the rugs and furniture, and I have saved ten feet of floor space." Reference to the block will show a pole with forked arrangement, which is for lifting the background from the wall and placing it in the hooked wires depending from the ceiling. This method seems an excellent one where the studio is large enough to admit of carrying an eight-foot square background about without its being rolled up, though it is possibly open to the objection that the backgrounds are hung all round the studio, and there tends to be too great a display of the appliances in what it is always well to keep as nearly like an ordinary room as possible.

### A Needed Revision of Development Formulae.

Some recent experiments having shown most clearly that development stain in a large number of cases is due solely to the use of a stale alkali solution containing sulphite of soda, we turned to the "British Journal of Photography" to see whether this combined accelerator solution is in common use. As a result we noted no less than twenty-five formulae in which such a mixture is prescribed. Four of these are ortol, and two metol, formulae, and we are unable at present to say whether the effect is detrimental or not in the case of these two developers. Of the rest four are hydroquinone, and fifteen are pyro formulae, which are the two developers we have more particularly experimented with. As these formulae are recommended by twelve of the best-known plate makers, it appears that the evil effects resulting from the mixture of soda sulphite with the alkali are by no means generally realised. For some reason or other, pyro stain seems now to be looked upon as an inevitable result of using pyro, though the falsity of this assumption must be evident to those familiar with the old-fashioned pyro-ammonia developer, which gave as clean negatives as anyone could wish for. As a matter of fact, stain can be just as easily prevented with pyro-soda if the sulphite is left out of the alkaline solution and put into the pyro bottle instead. A sufficiency of sulphite will always prevent stain, but sulphite that has been kept in solution with an alkali is quite useless. The same thing applies to the hydroquinone developer. A developer that has been made up for some time often turns a dark brown very soon after the two solutions are mixed, and it then stains the plate badly. This is commonly attributed to the deterioration of the stock hydroquinone solution, whereas it is really due to that of the alkali solution. With a fresh alkali solution the developer will work as well as ever, for the hydroquinone stock solution does not easily go wrong. As a stale alkali solution also serves, provided it contains no sulphite, it is evident that the sulphite, and not the alkali, is to blame. What happens to the sulphite when it is kept in combination with an alkali is by no means clear, but the fact is evident that it becomes useless as a preventative of stain, while the evidence points to some change that is actually provocative of that effect.

effects have been observed with sulphite solutions in their normal alkaline state without the addition of alkali, and these effects cannot be accounted for by assuming the gradual oxidation of the sulphite sulphate, or the gradual conversion of the sulphite carbonate. The sulphate is inert, while it is hardly possible for sufficient carbonate to be formed to produce the effects observed. The only things certainly evident about sodium sulphite is one of the numerous things we know little about, and that it has no business in an alkaline solution used for development.

**National Physical Laboratory.** In the House of Commons last week, in Committee of Supply, the sum of £10,000 was voted to the National Physical Laboratory for the extension of its premises and the completion of its work which has been contemplated for some time past. In proposing the vote, Mr. Haldane said the old Explosives Committee had ceased to exist, as it had been merged into the Chemical Research Committee. The higher scientific work which the Laboratory undertakes should be carried on only with the proper apparatus, and a grant would be of great assistance for this purpose. In comparison with the sums assigned in other years for the important scientific work such as is done on by the National Physical Laboratory, ten thousand pounds is not by any means a large sum. Mr. Haldane admitted that we were behind Germany and the United States in thus assisting the progress of industries based on scientific principles, and he evidently thought the task of impressing even upon Parliament the importance of such work was not at all an easy one. The Government, perhaps, will never properly realise the aid which a scientific and expert body can render to the chemical and mechanical trades, or why Germany finds it advantageous to vote to institutions such as the National Physical Laboratory grants which are the quadruple of those allotted in this country. The student of industrial chemistry will, nevertheless, recollect how certain industries exist in the first place to Government aid, and instances of the ways in which many branches of a trade have been brought into existence by the aid of research work of scientific experimental investigation be quoted in number. At present the relations of the National Physical Laboratory to the optical and chemical trades are not as intimate or as valuable as might be were more money at the disposal of the Government. But the great work which Dr. Glazebrook and his staff have done for engineering and electrical trades, and the hope that the day will come when practical photographic optics and chemical photographic manufacture will be able to benefit from the entrance of the Laboratory more actively into these fields.

#### SOME POINTS IN ENLARGING.

In an article which we recently published on the use of arc lamps it was pointed out that the professional worker nowadays needed to be independent of light as far as possible, and that it was especially necessary for many "one man" workers to be able to make their enlargements, speculative or otherwise, after daylight work was over. To the use of artificial light in enlarging there have been two objections. Where theoretically perfect optical conditions have been approximately approached, that is, a small point of intense light such as an acetylene flame or a well-constructed lamp, there has always been a danger of every blemish

in glass or film, even to the slightest finger mark or faintest smear of retouching medium, showing very prominently on the enlarged print. This precludes the possibility of using many, or, indeed, we might say any, of the masking devices, such as matt varnish, colour lightly dabbed on the glass side of the negative, and so on, devices which, as is well known, are often needed on portrait negatives, and may be used when making daylight contact prints with satisfactory results. The only method of masking which is practicable is the partial shading of the bromide paper during exposure, and to this we refer below.

The other objection really arises out of this, in the attempt to overcome it. By diffusing the light by means of one or more sheets of finely-ground glass placed between the illuminant and the condenser, the danger of these markings being present is much lessened, or practically eliminated, but the exposure is so increased as to be tediously long for the amateur and unprofitably long for the professional worker. By employing a more powerful illuminant, such as either an open, or preferably an enclosed arc lamp, it is possible to interpose a couple of sheets of ground glass, and obtain from average negatives enlargements to four or five diameters, using a lens of moderate quality, which might require stopping to  $f/16$  or  $f/22$ , to give sufficiently good marginal definition. If a modern flat-field lens of great intensity is employed, say an  $f/6$  anastigmat, then a sheet of selected opal glass may be substituted for the ground glass, and there will be still less chance of even elaborate masking with matt varnish and pencil retouching on this varnish making itself apparent on the enlargement. There is also much less necessity for accurate adjustment of the distance of the illuminant from the condenser, and as a consequence the focussing is more rapidly done and the risk of uneven illumination of the bromide paper greatly reduced.

The method of shading parts of the picture during exposure, referred to above, may be employed with either a moderate illuminant or with the more powerful one slowed down by means of the opal glass. It is simply a means of holding a suitably shaped piece of card or opaque paper in such a position as will shade the otherwise too dark part during a portion of the exposure. The difficulty of doing this ordinarily arises from an inability to hold the card sufficiently still, and at just such a distance that the size of its shadow is correct, and if two or three patches require to be shaded the difficulty is increased, unless there are two workers. By fitting between the easel and the projection lens a sheet of thin patent plate glass in a wooden frame about the size of the biggest enlargement usually made, it becomes possible to hold the masking papers exactly in position. The frame should be firmly fixed, enough to allow the paper to be cut or torn, and then held against the glass in order to ascertain if the shape and size are correct, yet it must be easy of removal during the exposure. Each separate mask must be attached to the glass, and as one or more may require to be removed before the others, the best method will be to use two tiny touches of a strong yet slow drying adhesive, so that when the mask is removed the paste on the glass will not throw any appreciable shadow. As a rule the glass will be placed at some considerable distance from the easel, so that the edges of the shadows of the masks will be softened. For the printing up of certain parts holes may be cut in a sheet of opaque paper and when the main exposure has been given the yellow cap is replaced on the lens, the small masking patches removed, and the second mask adjusted, when whatever additional exposure the denser parts of the negative requires can be given.

## THE PERSONAL ELEMENT IN FACTORIAL DEVELOPMENT.

It has often been suggested that a fatal flaw to the general scientific accuracy of factorial development is always present in the varying estimation of the time of appearance by different persons, or even by the same person at different times. It is argued with some show of truth that, with a long Watkins factor, the multiplication of any error in gauging the exact time of appearance will greatly increase the total length of development, thus producing negatives of undue density and probably untruthful gradation. The details of some experiments carried out recently by the writer, with a view to obtaining at least a slight clue to the chances and amount of error to be expected from the intrusion of the personal element, during the development of a given number of negatives by the average individual, may not be without interest.

### Conditions of Test.

It was recognised, in the beginning, that the only way in which any useful conclusions could be drawn must be by comparing the results obtained by a number of persons, working simultaneously, yet independently, and having entrusted to them for development plates of the same batch, exposed for exactly the same time on a given subject, the developer, the temperature, and all other factors being identical. A dozen negatives were therefore exposed on a typical landscape, choosing a time when the light appeared perfectly steady and unlikely to change. As the exposures were made in rapid succession with a magazine hand camera having an ever-set shutter, any difference due to change in light intensity during the operations must have been infinitesimal. The only chance of variation, in fact, lies with the shutter, but it seems improbable that exposures following so closely on each other, and necessitating no re-adjustment or alteration of the mechanism, can differ to any serious extent. The correct exposure was ascertained by means of an actinometer.

### Method of Observation.

In order to secure simultaneous development, it was decided to limit the operations to five individuals seated round a circular table at similar distances from a cylindrical ruby lamp; each of these having to flood his plate with developer at the word of command, and immediately to start counting mentally, the time being taken from the loud ticking of a pendulum clock. This, however, was only used for its convenience in judging the time of appearance, the total time of development being reckoned in each case from the observers' watches, which had been previously compared and found to have only a negligible difference in time-keeping properties. The observers had their dishes screened from each other by sheets of cardboard, and were supposed to note down their calculations silently and independently, and to withdraw and fix their negatives at the expiration of the estimated time of development. Of the five observers, No. 1 was a photographic expert; No. 2 had a fair acquaintance with photography; while to the remaining three the whole affair was entirely novel and had to be carefully explained before starting.

### Some Results.

A comparison of the resulting negatives and notes gave some interesting results. Two of the negatives would be called of correct density by most workers; one was a trifle too thin, but not to any great extent; and the remaining two were just a shade too dense. No. 5 had failed to flow the developer over at the right moment, so that there was a doubt whether his negative had been timed in strict accordance with the instructions. The degree of uniformity in the negatives was, however, much greater

than had been expected, and far more striking than differences. The exact figures obtained were as follows, metol-hydroquinone developer with a factor of 14:—

Observer No.	1	2	3	4	5	Time of	Duration of
						Appearance.	Development
	...	...	...	...	...	18 secs.	4 min. 12 sec.
	...	...	...	...	...	21 "	4 " 54 "
	...	...	...	...	...	23 "	5 " 22 "
	...	...	...	...	...	26 "	6 " 4 "
	...	...	...	...	...	25 "	5 " 50 "

Another five plates were now distributed, but the observers were not informed that the subject and exposure had been the same as before. This time the results were:—

Observer No.	1	2	3	4	5	Time of	Duration of
						Appearance.	Development
	...	...	...	...	...	22 secs.	5 min. 8 sec.
	...	...	...	...	...	23 "	5 " 22 "
	...	...	...	...	...	22 "	5 " 8 "
	...	...	...	...	...	26 "	6 " 4 "
	...	...	...	...	...	26 "	6 " 4 "

It will be noticed that a greater uniformity had now been reached, but that observers 4 and 5 were still a few seconds behind the others in noting the time of appearance. In spite of this, the negatives were remarkably equal in density, which seems to prove that some latitude in noting the exact time of appearance is allowable; at any rate, with a comparatively multiplying factor. It was also concluded that Nos. 4 and 5 would have got the same results as the others by using a shorter factor, and, the experiment being tried with the remaining two plates, this proved to be the case. The moral is, obviously, that when any worker finds that his negatives are, as a rule, too dense or too thin when using the multiplying factor commonly recommended, he has only to raise or lower the factor as the case may be, to obtain perfectly satisfactory results.

### Importance of Ample Light for Development.

So far, these experiments had been conducted with an allowance of bright ruby light, proceeding from a single source of carefully-tested red glass, which shed quite a full illumination over the dark room, while being perfect for any but panchromatic plates. It was decided later to test the variation in results, if any, which would be obtained in developing a similar series of identical exposures by the use of a deep ruby lamp of the old-fashioned type, in the dim gloom of which so many photographers are still content to grope. Under the altered circumstances some instructive results were obtained. Not one of the five observers agreed even approximately with the others in judging the time of appearance; the resulting negatives were either too thin (in one case) or much too dense; one negative alone could by courtesy be called of fairly correct density. It might not unfairly be deduced from this that some at least of the faulty results credited to the personal element are really due to nothing more nor less than insufficient dark-room lighting. One could use to judging density by the method of inspection in every worst of lights, but a half-hearted darkness of that kind is useless for the close examination and accurate comparison required for the successful working of the factorial system.

### Effect of Error with Greater Factors.

The previous tests were made with what might be called a moderate Watkins factor. It now remained to be seen what would happen when the factor is greater—as, for example, metol (30) or rodinal (40); where there is the additional possibility that the image appears very quickly and errors are more

made in judging the time of appearance. The result of series of experiments with several long factor developers led, however, to prove that, on the whole, the very rapidity of appearance which characterises them is, with ordinary care of observation, a safeguard against error. That is to say, the time comes out so quickly and unmistakably that an average intelligent worker can hardly be more than a fraction of a second in error without gross carelessness; providing, as before suggested, he is able to see what he is doing. Certainly, any one using factorial development with a high factor developer for the first time is apt to obtain some contradictory results; but little familiarity with the method of working soon overcomes this, and the operator is able to literally pounce on the time of appearance without hesitation.

#### Conclusions.

It would not, perhaps, be wise to dogmatise too much on evidence collected from a comparison of results obtained by small a body of observers. Still, the absolute independence of the latter, and the fact that the majority of them were practically unacquainted with photography, makes it fairly probable that the points in which the tests agreed would be fairly representative of what would happen in the case of

the average observer. The following conclusions it would appear, then, may not unjustly be drawn:—

(a) What is called the personal element is of comparatively small importance in factorial development, providing average care is used; being, in fact, much less evident and less likely to cause variation in results than with the old system of judging density by inspection.

(b) A liberal allowance of light in the dark-room (of course, non-actinic) is of the highest importance while watching for the first appearance of the image.

(c) Although a medium factor, neither too long nor too short, is probably preferable, there is practically no greater fear of variable results with a large developing factor than with a small one—given reasonable care in watching for and estimating the time of appearance.

(d) Some individuals are habitually quicker or slower in noting the emergence of the high-lights than others; but, as a rule, this variation is uniform, and may be allowed for by adopting a proportionally higher or lower factor for the same developer.

(e) Within limits, a slight error in judging the time of appearance will have no serious results. A. LOCKETT.

## THE CONGRESS OF APPLIED CHEMISTRY.

CREASED interest attaches to the meeting of the Congress of Applied Chemistry, held recently in Rome, from the fact that the year London is to be the venue of the members, the meeting hitherto having been held in Continental centres. On the invitation of Professor Tilden, representing the British Government, and of a committee elected by the members of the various British societies connected with chemistry, the Congress have agreed to visit London. The sixth meeting of the Congress was held in Rome from April 26 to May 3, and was under the special patronage of the King of Italy. The proceedings of the Congress were placed in twelve sections, dealing with the various branches of applied chemistry; Section IX., being confined to photochemistry, assembling under the presidency of Colonel Micheli, the president of the Italian Photographic Society in Rome, the most important society in Italy.

The meetings of the Congress were held in the New Palace of Justice, and the inaugural ceremony was attended by their Majesties the King and Queen of Italy, and their principal officers of State. The president was Professor Paterno, the honorary president Signor Annizzaro, and the secretary Professor Vittorio Villavecchia. Amongst those present in Section IX. were Professor Abegg (Breslau), W. N. Hartley (Dublin), A. Lumière (Lyons), R. Meldola (London), Seyewetz (Lyons), Sebelien (Norway), Dr. Vojtech (Prague), K. Freistadt (Vienna), Forel (Strasbourg), Joubert (Paris), Schmidt (Berlin), Dr. Castellani (Florence), and Dr. Eder (Vienna). The first meeting was held in the afternoon of April 27, and after the election of the president, Ernst Baum, emeritus secretary of the Società fotografica Italiana, Dr. Ludwig Castellani, professor of chemistry at Florence, and Dr. Lambert Loria, of Rome, were appointed secretaries.

The proceedings of the photographic section included a number of papers by authorities in different countries.

M. A. Lumière sent a paper on a "New method of photography in colours." Dr. Prokondine-Gorsky, of St. Petersburg, spoke on "Observations on the work in three-colour photography," and treated especially on the preparation and keeping of colour-sensitive plates. He bathed the plates in a weak ammoniacal solution of ethyl-red, pinacrome, and orthochrome, and recommended long continued washing in the bathed plates in distilled water in upright grooved tanks, with slow and continuous change of the water for three hours. The plates should be rapidly dried by an electric fan, and would then keep free from fog for a year. He also mentioned that plates kept in dark slides with glued-lined hinges fogged (especially in tropics) on parts opposite the hinges, and this he ascribed to the action of the glue.

Dr. Eder, in a paper "On the chemical nature of the latent image," sketched the current theories, such as the structure, molecular dissociation, photo-electric ionisation without reduction (see Report of the P.C.U.K., B.J., July 14, 1905, p. 551), and the sub-haloid theories; in the last the chemical reduction of the silver bromide being assumed. The latent image consists, according to his scheme of reduction,  $2 \text{ Ag Br} \rightarrow \text{Ag}_2 \text{ Br} + \text{Br} \rightarrow \text{Ag}_2 + \text{Br}_2$ , in which  $\text{Ag}_2 \text{ Br}_x - \gamma$  may also be used instead of  $\text{Ag}_2 \text{ Br}$ . The behaviour of the latent image, after fixation, to nitric acid, hyposulphite, potassium cyanide, ammonia, etc., was described. These phenomena can be best explained by the assumption of the formation of silver sub-bromide. (See B.J.P. December 1, p. 950, and December 8, p. 968, 1905). Silver iodide forms sub-iodide, which is decomposed by hyposulphite into silver and silver iodide, wherein it differs from the sub-bromide, which is only split up into metallic silver by potassium cyanide and not by hyposulphite. Similar processes take place in orthochromatic processes, as the silver bromide is forced to the same photo-chemical reactions in light of long wavelength by the sensitisers—that is, it is reduced to sub-bromide, as is peculiar to the unstained  $\text{Ag}_2 \text{ Br}$  in blue and violet light.

Professor Dr. Abegg, of Breslau, said that the reaction velocity in all these cases should be taken into account, and asked whether the reduced silver bromide of the latent image could not be influenced as regards its solubility in nitric acid by the surrounding of silver particles with silver bromide. Dr. Eder remarked that the latent image on silver bromide after fixation with hypo, whereby all the silver bromide would be removed, behaved always towards reagents like silver sub-bromide; but after fixation with potassium cyanide it behaved like metallic silver.

Professor Namias, of Milan, thought that the latent image was rather of a physical nature, that it was not sub-bromide, but polymerised silver bromide. Dr. Eder said that the phenomena of development of the latent image, after fixation, could not be explained by this theory, but only by the sub-bromide.

Professor Guntz, the renowned chemist, so well known for his discovery of the sub-fluoride of silver, considered that it was extremely probable that a sub-bromide was formed by light. He had synthetically prepared the sub-fluoride of silver from the sub-chloride, and the product behaved in a similar manner as Eder had assumed in his experiments on the latent image.

Professor Dr. Doelter (Graz) exhibited his photomicrographs of molten bodies at temperatures of 1,990 deg.—2,550 deg. Fahr., which created much interest. The substances, silicates, for instance, were melted in small quartz vessels in the electric flaming arc oven, and then photographed by means of a microphotographic apparatus,

fitted with a planar lens, cooled with ice water, by the glowing light which the bodies themselves emitted. Red filters and orthochromatic plates were used, and thus good pictures of the inner changes, such as crystallisation, etc., of the molten masses obtained.

The second day's sitting was opened by Dr. Eder, when Herr Freistadt, representing the Vienna Photo-Club, brought forward a well-intentioned motion that the great difficulties which were presented to artistic photographers in photographing open places and buildings in Italy should be to some extent lessened. This was unanimously supported.

Signor G. Giorgi, of Rome, then spoke of "The photographic function," by which he meant the connection between intensity of exposure and the density of photographic negatives. The lecturer spoke without any knowledge of previous literature on the subject (Hurter and Driffell, Eder's system of sensitometry, etc.), and showed a tube photometer with opal glass plate to diffuse the light, and used as a standard light an osmium lamp. Professor Bonacini drew attention to Eder's system of sensitometry and the tube photometers therein mentioned. Dr. Eder criticised the sensitometer test shown by the lecturer, and pointed out that the field of the instrument was very unequally illuminated, and seemed unsuitable for any measurements of opacity. Giorgi's photometer had too short tubes and showed faults which the older instruments of Roscoe, Hurter, Vogel, and Eder had for a long time obviated.

Dr. L. Castellani, of Florence, read a paper on "Experiments with a new emulsion of mercurous oxalate in gelatine," which agrees *in toto* with the paper by the same writer, entitled "Collotype with mercurous oxalate," published in the B. J. P. April 28, 1905, p. 332.

Dr. Prokondine-Gorsky (St. Petersburg) read a paper on "The position of photography, the photographic industry, and instruction

in photography in Russia," in which he advocated the establishing of a school similar to that in Vienna, which he considered the best of such institutes.

Herr Hans Schmidt, of the Neue Photographische-Gesellschaft, gave an address on "Three-colour photography with pinacol plates and tricolor carbon printing." The specimens shown excited general interest. An abstract of the paper appears below.

Dr. Giovanni Santoponte, of Rome, gave an address on "The value of photographic archives and museums of documentary photography and laid stress on the fact that unanimity should be established with regard to the printing process employed for reprints, and suggested the formation of an international commission. Dr. Eder thought that it would be difficult to come to any definite conclusion to such a commission at such short notice, and suggested that the matter be left to the Italian Photographic Society, Florence, or to the president of the same, for consideration at further steps. Colonel Pizzighelli stated that he was quite willing to take up the subject, and a motion in this respect was adopted at the meeting.

Dr. Eder then proposed a vote of thanks to the Reception Committee, which was accorded with acclamation; and Colonel Pizzighelli thanked the members, particularly the foreigners, for their attendance, and the meetings of the section were concluded.

The full text of the papers will, no doubt, be published in due course in the proceedings of the Congress, but we can now give those of several. Those by Valenta and Vojtech are translated from "Photographische Korrespondenz," for that by Professor Hartley we are indebted to the author, who very kindly sends the English version of his communication. Herr Schmidt has likewise sent us his paper in German.

### BROMIDE OF SILVER EMULSION FOR THE PRINTING-OUT PROCESS.

It is a well-known fact that pure bromide of silver darkens very rapidly in light, but not very intensely, so that it will not assume any intense colour; it is also well known that the blackening of silver bromide takes place much quicker in light, when certain chemical sensitizers are mixed with it. That silver bromide printing paper, prepared in an analogous manner to plain salted paper has found no practical use should be due to the fact that after fixing the blackness of the image is not satisfactory enough.

I have carried out a series of experiments, for the purpose of studying the behaviour of the same in the print-out process. These experiments, judging from the results, should be practically of importance, as printing papers of very good qualities may be obtained with collodio-bromide of silver emulsion. These papers print very quickly, the sensitiveness is more than double that of any good collodio-chloride paper on the market; they give a very rich scale of gradation and approach in this respect to albumenised paper.

The whites of the pictures are very clean, the brilliancy is very satisfactory, and the occurrence of bronzing, which is frequently very troublesome with collodio-chloride papers, has not been met with, even with very strong over-printing.

For the preparation of suitable emulsions I used calcium strontium, or lithium bromide, or zinc bromide, which was perfectly satisfactory. The quantities of the bromides are, if vigorous printing emulsions are required, to be so calculated that about half of the total quantity of silver should be combined (one can take 18 grms. of silver per litre of emulsion with 2.2–2.5 per cent. collodion); on the other hand, I used less citric acid than for silver chloride emulsion. Yellowish creamy emulsions are obtained which can be very easily and very regularly coated on paper, and which give the above described qualities. These papers print out a purple violet, and the prints assume a yellowish brown colour in the hypo bath. They may be easily toned in the separate or combined baths, and give reddish and purple brown photographic tones; they may also be toned, after preliminary treatment with dilute salt solution, in the combined gold and platinum baths.

From the experiments, the conclusion must be arrived at that the silver bromide collodion papers will soon take their place in practical work with the other present-day printing-out papers.

E. VALENTA.

### THE APPLICATION OF PHOTOGRAPHY TO THE SOLUTION OF PROBLEMS IN CHEMISTRY.

There can be no doubt that those rays in the spectrum of an element which cannot be readily recorded on a photographic plate are of little practical importance to the chemist; while, on the contrary, those which lie beyond the region of visibility are not only more numerous, but in general they constitute the most characteristic part of the spectrum of each element. An instrument which adds enormously to our powers of investigation is the spectrograph. In its simplest form it consists of a slit, two lenses, and a prism, all of quartz, in combination with a very accurately focussing camera. It records on a photographic plate the rays emitted by a substance whether they are luminous or not, and it arranges them in the order of their refrangibilities from wave-length 4,681 to 2,025, with all intermediate lines sharply focussed. By the use of isochromatic plates the less refrangible rays in the red may be simultaneously photographed.

The many and various problems which the chemist is called upon to solve may be considered under two categories:—1, Problems of composition, or analytical problems; 2, problems of molecular structure. I propose to give an account here of the applications of the

spectrograph to chemical analysis, the practical applications of organic chemistry being dealt with in Section IV. B.

#### Problems Connected with the Composition of the Atmosphere.

The spark spectra of the elements are individually composed of a great number of lines presenting different characteristics both in length, intensity, and shape, and it may be readily understood that an element can be identified by what may be termed its portrait. Out of 2,050 lines occurring in the spectra of sixteen solid elements not four can be found to occur in any two spectra.

Some lines which appear to be common to all the different spectra belong to the gaseous elements of the atmosphere, and their total number, as originally photographed, was 195. They were proved in 1887 to be due chiefly to oxygen and nitrogen, by photographing the spark spectra of metals in gaseous compounds composed of those elements; as, for instance, in nitrous oxide. But the spark spectrum of air as photographed, mapped, and described by Hartley and Adeney, contains various lines which could not be attributed to

or to nitrogen nor to any other substance.—("Phil Trans." Society, vol. 175, p. 63, 1884.) It had been observed that the atmospheric lines were subject to variations according to circumstances which were completely under experimental control, aluminium, indium, and copper electrodes, yielded air spectra lines more sharply defined and distinct and more prominent than others.—("Journ. Chem. Soc." vol. 41, p. 84; 1882.)

Facts were again studied in 1887 and 1890, but reserved for complete examination. In the year 1894 it was announced that Rayleigh and Sir William Ramsay had separated a new gas from the atmosphere. A proof of their paper, in advance publication, was forwarded to me from the Royal Society on May 29, 1895; this contained a description of the spectrum of argon. Sir William Crookes. All the lines he had measured of refrangibility than wave-length 4,629.5 were found in Hartley and Adeney's photographed spectrum of air, published in 1884.

Of these air lines out of a total of 195, which had been proved to belong to oxygen or nitrogen (Proc. Royal Soc., vol. 57, p. 193, 1893), were identified with argon lines. This fact with the actual wave-lengths of the lines, was communicated to the Royal Society at a meeting at which the papers describing the discovery were read. A letter from the Secretary at that time (Lord Rayleigh), now President of the Royal Society, informed me that the communication had been recognised as independent evidence of the existence of argon in the atmosphere. Eighteen days later I wrote out that the conditions as to pressure of the argon, and the use of the electrodes used in photographing the spectrum of air, were nearly those under which the brightest and purest spectrum of argon had been obtained. The spectrum of argon then had undoubtedly been photographed, and many of the lines accurately measured along with those of oxygen and nitrogen, for the first time in the laboratory of the Royal College of Science, Dublin, and published ten years later. Its existence was announced by its actual discoverers.

The most complete investigation of the argon spectrum was made by Eder and Valenta, and published in Vienna in 1896. On the basis of this page are shown the wave lengths and descriptions of argon in question, compared with the corresponding measurements of Crookes, and by Eder and Valenta. Eder and Valenta's were obtained with a Rowland concave grating of 30 inches focus, and those of Hartley and Adeney with a Rutherford plane grating of 17.296 inches, and quartz lenses of 36 inches focus.

Without the aid of photography it would have been impossible to establish the fact that the spark spectrum of air contained fifty lines which did not belong to the spectra of any of its known constituents.

The fact that argon gave two different spectra was considered to be evidence to the effect that there were two substances in argon, and before it was a compound. Evidence to the contrary was that many substances have two different spectra, and that had been photographed on the same plate, simultaneously from the same spark discharge, the two different spectra of nitrogen; namely, that there were no gaseous substances known which could give the high temperature of the condensed electric spark without exhibiting the spectrum of one or other of the elements of which it is composed. It was even argued that it was probably a modified form of nitrogen, even as ozone is a modification of oxygen.

As the spectrum of argon of either the blue or the red modification was not that of any known substance, it followed that if argon was a compound it must be a compound of a new element.

It was which was described as the true distinction between a compound and an elementary substance, with special reference to argon, was recognised as the criterion of an elementary form of matter at the International Congress for Pure Chemistry which met in Paris in 1900.

The absorption properties of the constituent gases and vapours in the earth's atmosphere cause the limitation of the solar spectrum, and the late M. Cornu, of Paris, showed that this limitation diminishes regularly, when photographs are taken at increased altitudes up to 2,570 metres above the sea level. In 1881 each of the constituent substances, known at that time to be present in the air, was examined, and the absorption effect on the ultra-violet spectrum of small quantities of each of them was carefully examined. The one substance which in minute quantities was found to cause the greatest amount of absorption was ozone, and

varying quantities above a certain limit caused the spectrum to be shortened almost exactly at the same point which was described as being the maximum absorption of ozone. This position coincided with the extreme end of the solar spectrum. The conclusion arrived at was, that neither dust in the atmosphere, nor the vapour of water, nor carbonic acid, nor any other vapour or gas in the atmosphere, save and except ozone, could cut off the sun's rays at almost the same wave length, and ozone must, therefore, be considered to be the cause of the limitation of the solar spectrum.—("Jour. Chem. Soc." vol. 39, pp. 111-128. 1881.)

The absorption capacity of ozone by the ultra-violet rays, within the range of wave-lengths 1,850 and 3,000, was recently measured by Dr. Edgar Meyer with Kreusler's photometer. He detected the absorption band, and located its greatest intensity at almost exactly the same point as was shown by my photographs. He also arrived at the same maximum of absorption.

(Edgar Meyer. "Über die Absorption der Ultra-violetten Strahlung in Ozon." Berlin, Inaugural dissertation, 1903.)

An analytical problem connected with the composition of the Dublin gas supply was in the first instance solved by the spectrograph. Coal-gas and oxygen burnt together in a blow-pipe yielded flame spectra in the photographs of which some of the groups of bands characteristic of cyanogen were identified. Dr. Eder, to whom we are indebted for so many and valuable spectroscopic and photographic researches, expressed doubts as to these bands being due to cyanogen, and accordingly very delicate chemical tests were applied

LINES in the SPECTRUM of ARGON photographed by Hartley and Adeney in 1884, compared with those of Crookes and of Eder and Valenta measured in 1895-96.

to the coal-gas, which proved absolutely the presence of cyanogen compounds in quantity quite sufficient to render its spectrum on a photographic plate.

### The Spectrographic Analysis of Alloys by Means of the Spark.

The quantitative spectrographic analysis of articles of ancient jewellery and coins is performed without removing any visible portion by cutting, filing, or dissolving in acids. Here are three examples of a Roman coin with the inscription Augustus Fortunatus, a Greek one of Alkibiades, and an obsolete French coin. The method of spectrographic analysis is extremely simple. A spark is passed from the coin to a piece of graphite and its spectrum photographed. The lines of the metals present are identified by comparison with the spectra of pure substances. The wave-lengths of the lines are measured, and the lines belonging to the different constituents are sorted out. The lines recorded indicate the composition of these two coins.

The Roman coin is a fine bronze, containing copper and tin with a trace of iron. The Greek one is peculiar, as, besides copper and tin, it contains lead and a larger proportion of iron. The coin itself has a peculiar golden colour. The composition of the "sou blanc" is of interest, as in some particulars it resembles the Greek coin. Neither tin, gold, nor silver was found—in fact, the coins were remarkably free from the latter metal. Its percentage composition is—lead 13.96 per cent., copper 72.35 per cent., zinc 12.70 per cent., and iron 0.85 per cent.

An alloy of this composition was made in the laboratory and rolled out; its spectrum corresponded exactly with that of the coin, in the length, strength, and number of the lines belonging to the respective metals. The quantitative composition of the alloy was then determined by the usual methods of chemical analysis, and the spectrographic analysis was proved to be correct.

The metal is peculiar, inasmuch as its composition is that of brass with one-third of the zinc being substituted by lead. It is apparently the large proportion of lead which gives the coin a golden colour, but prevents it having any metallic "ring." It may be remarked that the chief difference between the Greek and Roman coins is the quantity of lead in the former, and this diminishes the proportion of the copper.

A very troublesome piece of work was an investigation into the composition of brittle platinum, the metal being in the form of thin wire in pieces not exceeding 2 mm. in length. Such fragments could not be held in metal clips for the passage of the spark, because the spark of the platinum would be contaminated by that from the clips. The difficulty was overcome by fusing pure gold wires on to the end of the platinum with a blow-pipe flame, and with the gold wire as a conductor the spectrum of platinum was obtained free from any other metal. If the spark by accident happened to pass from the gold, the gold lines were easily recognised and eliminated from the platinum spectrum. Ten platinum pins were examined and the metal was proved to be free from any metallic impurity. From other evidence it was shown to be probable that the brittleness was caused by the presence of phosphorus. This investigation proved in a forcible manner—First, the utility for practical purposes of spectrographic analysis by means of the spark; second, the importance of determining the wave-lengths of arc and spark lines of pure elements with extreme accuracy; and third, the advantage of being able to distinguish between two spark lines of very nearly the same wave-length by the difference in their characters.

### Spectrographic Analysis of Minerals by Means of the Oxyhydrogen Flame.

By means of Deville's blow-pipe samples of various metallic elements and their compounds are easily volatilised, and may be submitted to direct spectrographic analysis. The spectra are quite different in character from those of the spark, particularly those of the metalloids and many of the metals, such as lead, tin, copper, silver, gold, antimony, and bismuth.

Iron, cobalt, and nickel give large numbers of lines, which are a characteristic feature in the spectra of meteorites. A collection of materials from iron smelting works, with a hundred and seventy iron ores and associated minerals from every part of the world were examined by Mr. Ramage (formerly of the Royal College of Science) and myself. Unsuspected and uncommon elements were found very

generally distributed through these ores in small quantities—instance, lead, silver, copper, chromium, and nickel, also the meals, rubidium, cesium, gallium, indium, and thallium. This last element is of rare occurrence in oxide ores, but frequently found in pyrites.—("Trans. Chem. Soc." 1897, and 547, and 1900, p. 61.)

Gallium was found in twenty-one out of fifty-one clay ironstones, and in all aluminous minerals, such as clays and bauxites, corundum. The siderites (ferrous carbonates) contain indium, no gallium, and the magnetites contain gallium but no indium. red hæmatites are remarkable above all other iron ores for purity.

From 375 grs. of the blast-furnace iron from the North-East Steel Works at Middlesbrough, in Yorkshire, there was extracted 0.0235 grs. of gallium sesquioxide. Undoubtedly the richest source of gallium now known is the pig-iron and steel rails made in the Cleveland district of Yorkshire. It contains one part of metallic gallium in from 30,000 of iron.

The thermo-chemistry of the Bessemer process was studied by photographing the spectra of the flames issuing from the mouth of the vessels in which molten raw iron is converted into steel. The flames exhibit peculiarities in different works according to variations in the process and the materials used. Photographs were taken every successive half-minute, the lines were seen to be increased in number, length, and strength as the "blow" progressed, and the temperature of the metal and the flames increased largely.

### The Examination of Atmospheric Dust.

In 1874 Baron A. E. Nordenskiöld described three kinds of dust collected by him. Two of these, which were found on the ice of the Arctic regions, were evidently of terrestrial origin, and could be accounted for, but the third variety was quite different, and appeared to be of cosmic origin. He arrived at the conclusion that this was meteoric dust, and that such was continually falling.

Small quantities of matter which had been precipitated from the atmosphere in snow, hail, and sleet, were submitted to spectrographic analysis by Mr. Hugh Ramage and me, and it was found that they contained the metallic constituents of meteorites. Pumice from the eruption of Krakatoa, which occurred in 1883, was also examined. Dust which fell into porcelain dishes placed on the grass, open to the sky, contained carbonaceous particles which looked like steel filings and were magnetic. Particles of soot were easily washed away, and the heavier particles were spectrographically analysed. Soot from various chimneys, and flue-dust from chemical and metallurgical works was examined. Several metallic and stony meteorites were also examined. The dust which had fallen directly from the clouds was distinguished by its regularity in composition; it appeared to contain the same proportions of iron, nickel, calcium, copper, potassium, and sodium. Volcanic dust differed from this in several particulars. Dust from sleet, snow, and hail suddenly precipitated from dark clouds again differed, and the difference was chiefly in the proportion of lead present, which in the dust from sleet was found to be much larger than in the other specimens. The conclusion arrived at was, that the dust which fell in November, 1897, was certainly meteoric, and that which fell in hail and sleet was of terrestrial origin, and most probably the product of chemical or metallurgical works. It was unlike flue-dust and not like soot in composition. The inference was that some of it was fume, such as is seen rising from the mouth of the Bessemer vessels. It was observed also that some of this dust contained a large proportion of lead.

The works near Dublin are not capable of causing dark patches in the sky at a very great elevation such as were seen before each of these storms. Whence came this fume? These darkening hazes in the sky were noticed always in an easterly or south-easterly direction. In South Wales, in the neighbourhood of Swansea, there is the largest group of metallurgical works in the United Kingdom where copper and lead are smelted and refined, and iron ores are smelted and the metal converted into steel. In the Vale of Dowlais clouds of fume arise from the Bessemer converters to a height of 300 or 400 feet in an unbroken column; the fume then rolls over and diffuses into the atmosphere, and with an easterly movement of the air, it disperses itself slowly over a large area and is borne away across St. George's Channel. Besides the South Wales district we have the manufacturing districts, known locally as the

black country," and "the potteries" of Staffordshire, also the chemical works of Lancashire, all contributing such fume, which rises over the Irish Sea when an easterly wind prevails, and travels to the interior of Ireland.

It might be supposed that the chemical works at the river side, near Dublin, may have contributed flue-dust, but that was proved to be the case, for flue-dust from the Dublin chemical works is distinguished by containing the metal indium, and none of the samples of dust from hail, rain, or sleet contained any trace of this metal.

Among other questions which have been solved by spectrographic analysis is the cause of the colour in slate. Three varieties were seen from the Bethesda quarry in North Wales, green, reddish, and blue in colour. The green colour was found in patches, and in every case where these patches occurred, the colour was undoubtedly due to copper, either as basic carbonate or silicate. The dark purple slates were found to be coloured by a manganese carbonate, and the blue slates, in addition to manganese, contain a small quantity of cobalt silicate. The direct analyses of galena and in Crossmaglen, Ireland, was made, chiefly to ascertain whether it contained any payable quantity of silver, for the information of the Department of Agriculture and Technical Instruction. Quantities of a gramme were burnt for each photograph, but the lines

of silver were so faint that the ore was reported to be of no value. A larger quantity was assayed in the usual manner, and the result led to the same conclusion. Associated with the galena was a cream-coloured, massive, crystalline mineral which, when spectrographically examined, proved to be very pure lead sulphate containing only a trace of potassium and a little copper, with a total absence of silver.

The unexpected occurrence of nickel in certain rocks, of strontia in a marine boiler incrustation, to the amount of one per cent., of lithia, and of beryllia in some of the granites and granitic rocks around Dublin have been proved by spectrographic analysis. For the examination of the absorption spectra of the rare earths, for testing methods for the separation of metals in quantitative analysis, and for determining the composition of small precipitates obtained in the analytic separation of substances, the spectrographic method is invaluable. I venture to predict that when the methods of working, and the practical details are more widely known, the spectrograph will become an indispensable instrument to the chemist, whether engaged in mineral analysis or occupied with organic research. Quartz and calcite are the only materials of use at present; the Jena ultra-violet glass when cut into a prism of 60 deg., transmits only so far as wave-length, 3,283 (Cd. 12); with calcite wave-length 2,194, and with quartz wave-length 2,025 are easily photographed.

WALTER NOEL HARTLEY, F.R.S.

### THE ACTION OF LIGHT ON ASPHALTUM.

The experiments which I will now briefly summarise, were made to explain the change in asphalt by light. If asphalt is exposed to light it becomes insoluble in certain oils of turpentine, which may be explained as a chemical or physical process, or a combination of two. From previous researches of Kayser it was assumed that the change was a physical one—namely, a polymerisation.

In order to determine what causes the insolubilisation of the asphalt by light, the following experiments were made:—Strips of glass tinted on both sides with 4 per cent. asphalt solution in benzole were exposed in various gases in a glass apparatus specially designed for the purpose, and the volume of the gases carefully measured under the usual precautions from time to time. The following gases, which were as pure as they could be prepared, were used, air, oxygen, nitrogen, carbonic acid, and hydrogen, and the following results were obtained:—

1. If asphalt is exposed in air or oxygen there is marked absorption of the gas, and the asphalt becomes insoluble.

2. If asphalt is exposed in nitrogen, carbonic acid, and hydrogen, the volume of the gas remains constant, and the asphalt is quite as soluble as if unexposed.

Parallel tests with dry and damp gases gave the same results. No difference was observed in the behaviour of the different kinds of asphalt, nor in the modifications of the same. It is interesting to note, heat acts on asphalt in an analogous manner to light, as if it be heated to 100 deg. C. it becomes insoluble. A return of the solubility by continued exposure or even solarisation was not observed. From these experiments we may conclude that most probably the process is a chemical one, for if it were polymerisation the asphalt must also become insoluble in inactive gases. A combination of a physical and chemical process is also excluded on the same ground, and one must therefore conclude that the process in the exposure of asphalt is of a purely chemical nature.

DR. VOITECH.

### THREE-COLOUR PRINTS BY THE CARBON-FILM PROCESS.\*

For a sketch of the early history and the various processes used in colour photography, the author recalled the fact that Ducos du Hauron in 1869 first used a carbon process for three-colour work, and that Vidal, of Paris, and Hoffmann, of Cologne (1893) also used it, but with only partial success, as they had to resort to double exposure. The method of coating the tissue on celluloid, however, introduced by the Neue Photographische Gesellschaft of Berlin, did away with this difficulty and considerably simplified the process.

The camera for taking the three negatives is provided with a rotating back, which carries the colour-filters immediately in front of the plates. The filters are not glass coloured in the mass, but of plate glass coated with coloured gelatine, and cemented to a covering glass with Canada balsam. It is impossible to obtain coloured glass which shall answer to the theoretical requirements, which are that not only should certain rays be absorbed, but the others must be transmitted in full intensity.

Flexible filters made of very thin sheets of gelatine may be used in the dark slides in contact with the plates, so that no special back is required. It has been proved in practice that it is not absolutely essential for these flexible filters to lie perfectly flat, so that no much stress need not be laid on this point. It is important, however, that they be kept perfectly clean and without creases, or marks will show in the negatives. The colour of these filters must be carefully chosen as that of the glass ones.

These flexible filters enable any camera and dark slides to be used without special arrangements, whilst the glass filters necessitate the use of the repeating back, which can, however, be fitted to

any camera with a ground glass. The latter arrangement has the great advantage that the changing of the plates and filters can be very quickly effected, which is of special importance in portraiture. For still life or landscapes the flexible filters are quite satisfactory, but they will not last long.

Although the exposure through the blue filter may be made on an ordinary plate, and then through the green on an orthochromatic plate, a panchromatic plate must be used for the red, and to obviate having to stock three sorts of plate it is as well to use a panchromatic plate for all three exposures, the results being also better as regards gradation.

The exposure for the three negatives can be easily calculated by anyone expert in ordinary black and white photography. If the N.P.G. plates and filters are used, the blue filter requires an increase of eight times under the same conditions without the filter, the green filter an increase of three times over the blue, and the red five times as long as the blue. These ratios are absolutely dependent on the plates and filters, and are quite independent of the colour of the object to be reproduced.

It is frequently more convenient to stop down the lens so as to obtain easily measurable times of exposure.

Although the above ratios are given, it will frequently be desirable to determine those for another kind of plate, and this may be done by taking a sheet of white paper, crumpling it up into a ball, and photographing this through the three filters till it is represented by equal density on all three plates. It is, of course, essential that all three exposures be developed together for the same time. As the plates are very sensitive to red, it is obvious that great care

\* An abstract of the paper by Hans Schmidt referred to above.

must be taken to prevent them from the red light of the dark room. It is better to fill the slides in the dark and to develop them in the dark; if this is not obtainable, one must be careful to work in the shade of the red lamp.

### Straight Development.

It may be asked how the development can be correctly controlled when it must be carried out in the dark, and cannot, therefore, be watched. The answer to this is that it is quite unnecessary in three-colour work, as errors in exposure cannot be compensated for in development. Development by time must therefore be adopted, and either a metronome or other device used and the seconds counted. With a developer of given constant composition and temperature, development will always be completed in a given time, assuming that correct exposure has been given, and this time may be easily found by a few experiments.

It is important that the developer and temperature used in the first experiments should be carefully adhered to in subsequent work, if good results are to be obtained. Above all things, it is essential, in opposition to ordinary photography, to pay great attention to the correct temperature, for two degrees less than the normal temperature—65deg. F.—will make sometimes a difference of over half the time of development. It will thus be seen what gross failures may be met with if exact methods are to be adopted. If, however, the conditions are strictly adhered to, development, "according to time," is very certain, and a great advantage in colour-photography, as one cannot be tempted to tinker about with the development of one plate in particular, a practice which would cause faults in the colour rendering.

The reason why it is not necessary to watch development in colour-photography is that one cannot see whether the negatives are correct or not, for we cannot say how much yellow, blue, or red there may be in a compound colour. If we take an autumn landscape, for instance, the red filter and green filter negatives will look approximately normal; the blue filter negative will, on the other hand, look completely under-exposed. But this is as the negative should be, for there is always a lot of yellow in the autumnal tints, and, therefore, the blue filter negative, which is printed in yellow, must be very strong.

Three-colour negatives should be thin and soft, for whilst, on the one hand, the gradations must be as delicate as possible, the three negatives must not be printed so deeply as in ordinary work, because three prints are superimposed to make the final result. If there is any white object in the subject, this must be equally dense in all three negatives, and yet not so dense that it will not print through.

With some subjects, portraits, for instance, of sitters in brown, grey, or neutral coloured clothing, very little difference can be seen in the three negatives in subjects with strong colour contrasts; on the other hand, the difference is very striking. In order to avoid mistakes later in the printing, it is advisable to have some distinguishing marks either on the filters or on the dark slides, which shall be automatically impressed on the plate during the exposure. It will thus be easy to distinguish which are the different negatives.

As regards the developers, soft working, rapid developers like rodinal and edinol should be used; in no case hydroquinone. As the time of development is very short—only about half the normal—care must be taken to cover all three plates at once with the developer, and to remove them from the developer as soon after one another as possible, as errors may even be caused here.

After development the plates should be well washed and fixed in an acid fixing bath, and only when thoroughly fixed exposed to white light. Intensification or reduction should be avoided as much as possible, so also should all retouching.

### Printing from the Negatives.

The system adopted for printing is that of the N.P.G. stripping carbon tissues, which are gelatine, with the pigmented gelatine coated on thin celluloid specially prepared with a film of rubber previously. These films must be sensitised in a bichromate bath, the strength of which must be adjusted to the character of the negatives—for instance, for vigorous negatives a 6 per cent. bath should be used, and for soft negatives a 3 per cent. The great

advantage of this process is that the celluloid is placed in contact with the film of the negative in printing, so that there is no double transfer.

As with all pigment processes, an actinometer must be used, and for this a bichromated paper must be used, and not a P.O.P. The reason for this is that the two behave quite differently, and thus the quality of the final print may be unfavourably affected. Silver papers are chiefly sensitive to violet, while chromated gelatine is principally affected by the blue rays, with the result that the pigment films may be considerably overprinted before the silver paper has reached the requisite degree.

The development of the tissues is effected with warm water, and with all other carbon tissues, only this should not be too warm and development be slow.

The great advantage of the N.P.G. process is that the three constituent prints are not, as with all other processes, prepared one after the other, but simultaneously, so that one may easily see by temporary superposition as to whether the colours are correctly rendered, and alter one or the other to suit. For instance, if we have to photograph a white marble hall—for instance, the throne-room of the Imperial Castle in Berlin, which has a gold ceiling—in places this will be reflected by the white marble, and we can specially develop these places so that the marble is rendered white.

When the three constituent prints are found to be correct, we may proceed to make the paper print. The yellow tissue and a piece of transfer paper should be immersed in warm gelatine solution, the two squeezed into contact and allowed to dry, which will take from six to eight hours. Then the celluloid can be easily stripped, because of the layer of rubber. The print must now be rubbed with benzole to remove the latter. Then the blue print and yellow should be immersed in gelatine solution, squeezed, and hung up to dry. The trouble of making the two images coincide is very little, for they are not examined by transmitted light. The red print is superimposed in the same way.

As regards the lens, from a theoretical point of view this should be an apochromat, but as a rule these only work at  $f/10$ , which is quite large enough an aperture for outdoor work, but not for that in the studio; it is preferable, therefore, to use one of the modern anastigmats. Even the simplest objectives may be used if of sufficiently long focus and small sized pictures only are made. Under these conditions, an old Petzval portrait lens may be used quite satisfactorily. It certainly is not necessary to purchase a new lens for three-colour work. Periscopic, bistigmats, and the cheaper aplanats are alone excluded.

As regards the non-coincidence of the images, obviously the subject must not move much during or between the three exposures; but if the leaves of a tree should move, it is not of much moment, as the only result will be somewhat less sharpness of detail, but not incorrect colour-rendering. If a person should move, however, there will be want of sharpness and incorrect colour-rendering. As regards the movement of the camera during the changing of the plates, too much stress has been laid upon this, for if the camera does shift during the changing of the dark slides, it can only be to the right or left, the distance between the lens and sitter will be the same, and, therefore, the middle of the pictures will coincide, and it is only necessary to cut a little off one or other of the sides.

The statement that correct colour mixtures cannot be obtained by the superposition of three separate images, and that they must be in one film is incorrect, for the coloured tissues merely act as filters, and it is immaterial whether a green is made up of one film or of a blue and yellow. As regards the printing through the celluloid, there is no want of sharpness caused by this, as it is so thin as not to make any difference.

It should also be noted that a razor-like sharpness in colour work is highly unæsthetic, and therefore generally some little softness should be aimed at; this is, however, very easy to obtain in superposing the three pigment tissues.

HANS SCHMIDT.

The Council of the Society of Arts has awarded the Albert medal for the present year to Sir Joseph W. Swan, F.R.S., "for the important part he took in the invention of the incandescent electric lamp, and for his invention of the carbon process of photographic printing."

## HANGING BACKGROUNDS.

recent issue of "Wilson's Magazine" (New York), an old American professional, Mr. A. W. Judd, of Chattanooga, Tenn., the following description of the system adopted by him for hanging of backgrounds in the studio:—"For over forty years," says Mr. Judd, "I have been taxing my patience with the fastidious of the backgrounds—they are so unsightly, noisy, and require so much time and room to arrange them. I took some wire one-eighth inch thick, with curved ends and hung from the ceiling in screw eyes. Into these hooks, I put ordinary curtain poles

the backgrounds tacked to them, another pole tacked to the wall, or the extension rolled, and buttoned curtains with hooks to adjust them to any pole or background. Wires were hooked to the headgrounds so as to hook them to any pole. In this way I changed my backgrounds with ease and rapidity, without any trouble and without disturbing the rugs or furniture. By discarding the old background frames and feet I have saved 10 ft. of the wall space, and am able to make the room look much more attractive at all times."

The illustration shows the arrangement adopted by Mr. Judd.

## A BUSINESS STIMULANT.

REFERENCE was recently made in our columns to the experience of an American photographer, Mr. Giffen, of Wheeling, in running a children's contest. As the scheme was found to have brought him a great deal of business, we may quote the substance of Mr. Giffen's announcement. The letterpress is surrounded with pictures of former prize winners, and printed on a large sheet in brown ink:—"It is the duty of every parent to get the best pictures possible of their little ones while they are in health. The neglect of this has caused deepest regrets

Prize Children's Contest.

\$50.00 IN GOLD. \$50.00

Three Prizes for the Three Best Pictures of Children

Under Ten Years of Age.

It is an opportunity that no mother, proud of her little one, can afford to lose, as we will put forth our best efforts in making every child a prize winner. Therefore each one will be a gem, whether it is a prize or not.

The following noted men of international reputation will act as judges, and our reputation being at stake in the eyes of these experts, as well as the public at large for these contests will necessarily attract universal attention, every subject will receive our most sympathetic consideration. Burr McIntosh, noted photographer and critic of New York; Sydney Allen, lecturer and writer of New York; and one capable representative of our own city.

Each picture would be of priceless value to any parent in after years—a sweet, fadeless record of the little baby's face and form, lasting longer than memory.

No better time than the delightful months of May and June could be chosen for taking children's pictures, as they then may be dressed in those loose, dainty summer garments, so essential to the artistic make-up of a child's picture.

Bring them at once, before the oppressive heat of the summer season shows its enervating effects upon these priceless little flowers of nature, and we will assure you that the resultant picture will go beyond your anticipation.

As a matter of further interest, we are pleased to say that our work, being so well known by the management of the leading periodicals, that we are often called upon by them to enter such examples of our children's pictures as we see fit for prize in their frequent children's picture contests, in which many prizes are given, amounting to thousands of dollars. We do not derive any financial benefit from these affairs, as prizes, thus awarded, are sent in full to the prize winner. Such an acknowledgment of our painstaking efforts and the compliment to the subjects are ample compensation for us.

We ask you to bear in mind that this contest closes June 30th, and that you should not put off having the sitting made, and thus be disappointed, as were many in our last year's contests.

Our prices are from \$5.00 per dozen and upward. We will allow a special reduction on all work up to the first 100 sittings.

Yours for the Best in Photography, J. E. GIFFEN,  
Studio, 42, Twelfth Street, Wheeling, W. Va.

## IS SPIRITUALISM A FRAUD?

THE challenge offered to Mr. J. N. Maskelyne through the "Daily Express" has been accepted. Readers of that journal will know that in confronting Mr. Maskelyne, Archdeacon Colley, as the champion of the spiritualistic phenomena, "challenges Mr. Maskelyne for £1,000 to do in any way, anywhere, and at any time, as a conjurer, what the St. George's Hall illusionist declares Dr. Monck did by trickery, as reported of spiritualism in a lecture entitled 'Phenomena, Bewildering, Psychological.'" The matter has led to the publication of several letters in the "Express," of which the following may fairly represent the justifiably agnostic attitude which photographers take in regard to alleged spirit photographs:—

SIR,—Spiritualism as we know it to-day was, I believe, originated by the sisters Fox, of New York, in 1849, and reached our shores three years later. From that day up to the present photographs of what are claimed to be spirit forms have been produced in shoals.

While we have several photographers who look upon some, if not all of them, as genuine, quite 99 per cent. of those who know anything at all about photography look upon them as frauds.

It has been proved repeatedly that things invisible to the naked eye can be photographed, and the sulphate of quinine test is, perhaps, the best known. One has only to take a little of this clear, water-like solution and sprinkle or paint it on the object to be photographed—say, the face or background—to obtain the most grotesque and startling effects, for, although invisible to the naked eye, it will distinctly show in the photograph.—[? Eps., B.J.P.]

This fact alone—and there are many others—convinces some that spirits, if they exist, can be photographed; hence the pictures.

One of the books on spirit photographs makes much of the experiments carried out by the late J. Traill Taylor, who was editor of one of our leading photographic journals. Mr. Taylor, in March, 1893, got something of a spirit form on his plates, and he read a very instructive and convincing paper on the subject. (See "British Journal of Photography," March 17, 1893.)

Spiritualists make much of Mr. Taylor's experiments, but they carefully abstain from saying that, before his death, he deeply regretted publishing it, for he came to the conclusion that he had been "duped."

Spiritualists have many times been asked to give a sitting to a body of picked photographic experts, but they have always made some excuse, and a sitting, up to the present, has never been granted. A committee composed of, say, E. J. Wall, T. Bolas, A. Haddon, P. R. Salmon, G. E. Brown, A. L. Henderson, R. C. Bayley, and a few others would soon settle once and for all whether there was anything or not in so-called spirit photography.

I have met many mediums in my time who would consent to a sitting before a single camera or worker, and, where possible, I have secured them; but, although I have spent many pounds and

exposed hundreds of plates, I have obtained no results. Neither do I know of any other worker who has, when he has made his own conditions, one of the conditions being not to allow the plates to leave his hands.

The last medium I employed was supposed to be one of the best. I fulfilled all his conditions as to draping the room—my own room, be it stated—but I got no spirit forms upon my plates, even though he stated that they stood still long enough to be photographed.

He said he could see them, and, in fact, spoke to them, but I could not. He, however, told me where to focus, and had they been present, their light, misty forms, as he said they were, must have shown upon the sensitive plate, for the room was hung with black and dark-red curtains, which would not show in the photograph.

There has never yet appeared a spirit photograph which is at all convincing to photographers. All the so-called mysterious markings and forms can be explained and easily produced by imperfect work or trickery.

In conclusion, let me ask spiritualists, particularly those interested in the photographic side of the question, a few questions:—

(1) How is it that spirit photographs when taken stereoscopically do not stand out in relief, like the rest of the picture? Mr. Taylor himself said ("The Veil Lifted," p. 33): "... The impressing of the spirit form was not contemporaneous with that of the sitter ... I carefully examined one in the stereoscope, and found that, while the two sitters were stereoscopic per se, the psychic figure was absolutely flat ... the psychic figure was at least a millimetre higher up in one than the other."

(2) Why is it that ordinary monocular spirit photographs have such a "cut out" look about them—"as if," to quote Mr. Taylor again, "an atrociously badly vignettted portrait, or one cut oval out of a photograph by a can-opener, or equally badly clipped out, were held up behind the sitter?"

(3) Why is it that spirit pictures of celebrities who have "passed over" are exactly like—copies, in fact, of—published portraits of them? Surely if they still favour us with sittings some photographer would be lucky enough to get a new pose of one or other of them. Spirit pictures of, say, Dickens, Scott, Wordsworth, etc., are all exactly like the well-known portraits of them. The much-talked-of spirit photograph of Dickens is exactly like one which appeared in the "Illustrated London News" at the time of his death.

(4) If mediums are so confident that spirit forms exist and can be photographed, why do they not let a qualified expert do the work? Nowadays only photographers who are spiritualists themselves get "satisfactory" results.

(5) Why has not a spirit picture of Mr. J. Traill Taylor been produced? We who knew him and all his pictures could soon tell whether the pose was new or not. He promised his most intimate friends before his death that if spirit photography were possible he would appear on the plates exposed by some of his friends—but no spirit picture of him has appeared.

A FELLOW OF THE ROYAL PHOTOGRAPHIC SOCIETY.  
London, E.C.

#### ANACHRONISMS IN ART.

THE "Dioptric Review" is, in its present issue, rendered unusually attractive on account of the reproduction of a work by Rubens, and of a smaller illustration of one of the heads in the picture circumscribed with the utmost decorative effect. The subject is that of the Magdalen washing the feet of Christ with her tears; and the head separately given, that of one of the Apostles. A note accompanying the prints affirms the "special interest of the picture" to be the "obvious anachronism of one of the Apostles wearing a pair of pince nez." To a dioptrician this may be so; but to one who is neither that nor a dry optician there are points of greater interest in the work. The note also states that "Dr. Bock in, a recently issued book, gives no less (no less!) than ninety-four examples of well-known pictures where artists have depicted people of over one thousand years (*sic*) as being in the possession of spectacles." We cannot see what delight spectacles can find in possessing people of over one thousand years, and we think they ought to relinquish ownership in favour of the churchyard!

We are inclined to believe, moreover, that Dr. Bock's research must have meant an easy time for him. Had he found ninety-million anachronisms the fact would have caused less surprise. The very picture under discussion the so-called pince-nez are, of but a grain of sand from the shore. It is "special pleading" to them such a modern name. In reality they are "folders"—a which saves them a few centuries of the crime they are charged with. If this unfortunate picture were thrown to any of specialist organ, say "The Tailor and Cutter," what growls and tearings might not ensue. Or if to the "Cabinet Maker" and "Barber's Journal" what would be left of it? Viewed from proper point of view, Peter's folders are the least anachronistic any detail in the whole composition. They were what Rubens himself saw every day, whereas these flowing robes were, to him, p conventions of the imagination, and as foreign to the ancient Hebrew as to the painter himself.

The spectacles are worn by the Apostle so that he may appear more emphatically to be overcome with indignant surprise—not be able to believe his own eyes. This is the higher realism, and the truth of impression to be a matter of more moment than the truth of fact for mere fact's sake. The writer of the note will be surprised to know, perhaps, that at the Grafton Galleries he may see a lot of modern German peasants listening to Christ preaching. Still anachronisms are adopted for expediency, and so was this one of Rubens's, which appears to be thought the outcome of ignorance.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents were made between May to June 2:—

**COLOUR PHOTOGRAPHY.**—No. 12,793. Colour screen for multiple colour photography and provided with spaces for comparison. Charles Louis Adrien Brasseur, 18, Southampton Buildings, London.

**FINISHING SHEETS.**—No. 12,806. Improvements in processes for finishing photographically printed sheets. Charles Francis Peasgood, 111, Hatton Garden, London.

**PANORAM CAMERAS.**—No. 12,813. Improvements in panoramic camera. August Muller and Johann Klein, 111, Hatton Garden, London.

**THREE-COLOUR.**—No. 12,864. Improvements in three-colour photography and the projection in natural colours upon a screen of aluminium. Henry William Hamblin Palmer, 43, St. Martin Lane, London.

**FILM-PACKS.**—No. 12,887. Improvements in adaptors or carriers for using film-packs, change boxes, film envelopes, dark slides, and the like in photographic cameras. John Edward Thornton, Altrincham, Cheshire.

#### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**DEVELOPING FILMS.**—No. 18,551. The claim is for a developing dish of which a tongue or bar (under which the film is drawn), forms an integral part; also for a scoop-shaped end to the well of the dish, to facilitate the insertion of the film. Frank Sugg, 12, Lord Street, Liverpool.

**NATURAL BACKGROUNDS.**—No. 27,088, 1905. The invention relates to the production of composite photographs, such as figure subjects, with any desired background in which a double exposure is given to the subject; in the first instance, as a silhouette against a white background, and through a positive picture background transparency, placed in proximity with the sensitive plate; and in the second instance as a light reflecting body against a black background, but without the picture transparency. It has been proposed to take a composite photograph by the wet plate process of photography in substantially the manner above described, but in carrying out such process it was necessary that the positive picture background should be prevented from coming

into contact with the sensitive plate, and special means were employed for this purpose. Hence no sharpness of the picture background was possible in the finished photograph. Further, the manner of lighting was imperfect, and in conjunction with the low sensitiveness of wet plates rendered the process impossible as a commercial one. According to the present invention, a sensitive dry plate is employed, and the picture transparency is placed in actual contact with it, so that the picture background can be clearly and sharply brought out thereon, and further by the illumination of the model or subject by artificial light, such as flash light, both accuracy and rapidity in carrying out the process is attained. The specific claims are:—

1. A process for the production of composite photographs, in which a picture background in the form of a positive transparency is placed in contact with the sensitive dry plate. 2. The process as described in the preceding claim, but in which the model or subject is illuminated by a flash or artificial light. 3. For carrying out this process according to the preceding claims, a plate carrier, consisting of a hinged frame adapted to hold the positive picture background in contact with the sensitive plate during one exposure, and to let it fall or move out of the path of the light rays falling upon the sensitive plate during the other exposure. Frederic Julius Dischner, 150, Norstrasse, Zurich, Switzerland.

PRINTING FRAMES.—No. 1,563, 1906. This invention relates to an improved construction of photographic printing frames, used in taking successive prints from a negative without removing the paper from the frame. This type of frame is employed especially for rapid printing of small photographs, arranged in a series on a long plate, and a single large sheet receives usually twelve successive prints of the entire series. Such plates are marked with a number against each photograph, which number is printed on the sheet at the end of the series of exposures, to identify the different photographs, and my invention relates more especially to means for effecting the special exposure at the proper time without requiring special attention. The main frame is provided with two slides, having ledges to receive the plate, the lower slide being, as usual, adjustable by means of a slot and thumbscrew or the like, while the upper is controlled by a spring, and moves only a distance sufficient to expose the numbers on the plate. The sliding frame receiving the sensitive paper is moved into its successive positions for printing, and at the end of a complete operation presses up the upper slide and exposes the numbers on the final print, means for adjusting the point at which this occurs being provided. An adjustable bar is also used, against which the end of the plate abuts, but in case no numbers are on the plate the bar is lowered to allow the full width of negative to be exposed. Marwood Short, 1, The Collonade, Ramsgate.

NEW FILMS.—No. 10,394, 1905. The invention consists in constructing a continuous opaque band, capable of carrying upon itself the means of holding the flexible cut photographic films or sheets of any make, so that they can be readily and correctly attached for exposure, or as easily removed for development after exposure, and which can be rolled without injuring or crinkling the films, for which purpose it is essential that a certain degree of extensibility shall be given to the band, enabling it to accommodate itself to the varying length which the band and its attachment devices occupy when rolled with the films in place. To facilitate rolling without buckling it is proposed to transversely corrugate or groove the complex non-actinic band and its attachments, but occasionally sufficient elasticity can be realised by corrugating only the band or only the attachments. It is not essential that the grooves or corrugations should be strictly parallel, a somewhat irregular "crinkling," like that of certain Japanese papers, being found to give satisfactory results. William Fraser, Cloughton Kelley, 22, Winchenden Road, Fulham, S.W.; and John Arthur Bentham, 51, Claverton Street, London.

The following complete specification is open to public inspection and acceptance under the Patents Acts, 1901:—

EMATOGRAPHIC FILMS.—No. 11,762, 1906. Compagnie General de Photographes, Cinematographes, et Appareils de Precision.

## Exhibitions.

### PHOTOGRAPHS BY HENRY STEVENS.

THE collection of photographs of flowers and domestic pets now arranged on the walls of the little gallery at the offices of the BRITISH JOURNAL OF PHOTOGRAPHY does not number fifty in all, yet it represents a career in photography which many would be proud to point to as their own. The photographs are known, of course, to those who saw them at the Royal Photographic Society about seven years ago, but to very many of those whose adoption of the camera has been since the rise of modern amateur photography, with its many aids to lighten labour, the photographic work of Mr. Stevens must come as an achievement utterly beyond their powers. And the fact is it represents something more than the ability to use tools and materials which were less perfect ten years ago than those obtainable to-day. It represents the possession and exercise of infinite patience, and a mastery of photographic processes which comparatively few amateur photographers of the present day have the time or inclination to cultivate. For these reasons the photographs should possess an interest to every amateur. They hold out a standard which challenges the beginner, and may discourage him by showing him the gulf which separates such splendid work from his own productions.

Mr. Stevens, it is true, had the good luck to approach his photography as a lover of the country and a resident on an estate in one of the most beautiful parts of Surrey. The photographs of flowers and animals reproduce the surroundings of his home near Weybridge, and though such opportunities do not come to everyone, they do not confer the ability to photograph subjects with such an approach to absolute realism which one finds in the pictures on the walls in Wellington Street. "It is wonderful photography," is usually the first exclamation of anyone who is accustomed to see photographs good, bad, and indifferent. And the beauty of the flower studies becomes all the more remarkable when it is known that Mr. Stevens has never used an orthochromatic plate. The secret of the exquisite renderings of lilies, ferns, and orchids is in the ample exposures given and the restraint practised in development. The lighting of the subjects in the first instance has been equally the work of a practised hand, otherwise it would be impossible to produce such a photograph as No. 19, where some water is shown collected on a jar of chrysanthemums so realistically that the first impression is that the print itself has been sprinkled.

No less wonderful than the flower photographs are those of the cats, rabbits, and dogs. Some of the dumb sitters are, or have been, Mr. Stevens's own pets, and had therefore become accustomed to being photographed. But others were strangers to him at the time of the sitting, and the equally faultless rendering of their characteristics suggests that training is not the open sesame to animal photography. In fact, Mr. Stevens will admit that there is only one royal road to success in photographing such subjects, and that is the determination never to give in to your sitters, and the patience to carry out the resolve, however long it may be before you get your own way. Animals come at length to understand that it is useless their holding out any longer, and though the process of preparing them for the exposure of the plate may last half a day, the moment arrives when the cap may be removed and a negative may be made which possesses a quality impossible of attainment by a number of "snap-shots" taken on the chance that all will be well when the plate is developed. This experience of Mr. Stevens may be worth repeating for the benefit of those who will examine his photographs. There is no occasion, he has found, to expose plates on the chance of the result being good. In his own work it has rarely happened that he used a plate without feeling confident that the group of sitters was happily composed, and that they were likely to remain still for the time necessary for a cap exposure to be given.

The reproduction of one of the flower studies which we present this week gives a fairly good idea of the quality of Mr. Stevens's work, but the majority of it must be seen in the original for a proper appreciation to be formed of its merit. The realism of the photographs is their chief qualification for the epithets which we have used in reference to them, and that precise quality cannot be com-

municated through the half-tone block. Some transparencies from negatives of subjects similar to those shown as prints are exhibited in the windows, and will, we hope, be noticed for the extremely favourable way in which they reproduce the gradations of the negative, and for the proof they adduce that "fake," so glorified by the modern photographer, has no part or lot in the work of Mr. Stevens.

## New Apparatus, &c.

The Welborne Piper Photographers' Stop Clock. Sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

This instrument has been introduced not only for the so-called "time development," but for many other photographic operations the accurate control of which in regard to time will be accompanied with advantages in the matters of quality and regularity. The mechanism and adjustments of the clock are a little difficult to explain, but reference to the diagram should make clear the facilities which it offers in aiding the photographer to time his operations in the dark room.

F. Starting lever.

H. Bolt by which the setting of the clock is made either "time" or "bulb," i.e., by which the clock will either continue going after the lever F has been depressed and released, or will go only while F is kept down.

M. Pneumatic bulb for release to replace the lever F and answering in the same way to the movement of the bolt H.

G. Stop-lever, pressure on which stops the clock.

D. Gong lever, to permit of, or prevent, the minute gong from striking.

E. Automatic stop. On turning the screw downwards the seconds hand of the clock is arrested at the zero position.

There are two ways of setting the clock for use. It may be arranged to work by "time" or "bulb." The former we find the more convenient method, but care should be taken by users to familiarise themselves with both if they would understand the working of the clock and be able to avail themselves of all its movements. To set for time, the bolt H is pushed in towards the letter T on the wooden case of the clock, and the clock then stopped either with G or with the automatic stop E. Sharp pressure on the bulb, or on the lever F, will now cause the clock to start, and

it will continue to go until stopped, striking the gong at every completion of the minute—that is, at every time the seconds hand reaches the zero point. A second pressure on the bulb stops the clock only for the time the bulb is kept pressed. To stop the clock permanently the lever G must be depressed.

For the so-called "ball" setting the brass bolt H is pulled towards the letter B marked on the wooden case. The clock then starts upon the bulb or the lever H being pressed and continues running only as long as either is kept pressed. The clock thus set to "bulb" behaves just like a photographic everset shutter also set to "bulb."

The above description, perhaps, will scarcely fulfil the purpose we have in writing it, viz., to show the ease and convenience with which the clock is used. Perhaps we can do this better by pointing out the applications of the instrument in practical photography. Take first the "timing" of development by the Watkins factor method. The clock is set to "time," and the bulb of the release placed beneath the worker's foot, the 4 ft. length of tube permitting of this being done. The clock is started from zero, the moment the developer is poured on, by sharply pressing and releasing the bulb, and the clock is arrested by pressure on the bulb the moment the image appears. The number of seconds which have elapsed during the appearance of the image can thus be read off accurately to half a second, and the total time of development thus obtained with equal accuracy.

Next take the case of such work as copying, photographing with the microscope, etc., where the exposure may have to be interrupted several times in order to avoid vibration from passing vehicles. The bulbs of the shutter and the clock can be pressed simultaneously, and the intermittent exposures thus made conveniently, whilst the clock adds up the separate times and prevents the occurrence of errors which are most difficult to avoid if the exposures are made with an ordinary watch. The clock and shutter, if preferred, can be worked off one bulb by providing a T piece, but this addition is not absolutely necessary.

In such work as the above the advantages of the clock are patent, yet in other branches of photography, such as enlarging, the uses of a convenient instrument for timing not only exposures to light but the duration of washing, toning, fixing, etc., make for greater certainty and regularity in the production of photographs on a commercial scale. In addition to the movement providing gong indications of each minute—a provision which enables the clock to be used for time development in absolute darkness—the clock has the usual alarm gong, which is set and used in the ordinary way, and by which the time at which to remove prints or plates from the washing tank is forcibly emphasised to the photographer. For all the purposes for which we have had occasion to use the clock during our short possession of it we have found it answer to the maker's instructions. It is evidently well and accurately made, and we believe that its performance is afforded a reasonable guarantee in the personal examination which Mr. Welborne Piper makes of each instrument before it is handed on to the purchaser. Messrs. Butcher may congratulate themselves that the introduction is one which should be appreciated by large numbers of the more serious practitioners of photography, to whom the price of the clock, 30s., should soon be returned in the time saved and the supervision of photographic processes which it assists.

A convenient accessory for the enlarger and copyist has been introduced by the Tress Company, 205, Oxford Street, London, W., under the name of the "Combination Enlarging and Copying Frame and Bromide Paper Storage Box." This comprehensive title is almost self-descriptive, but it remains for us to say that the apparatus consists of a shallow box fitted with a self-catching light-tight lid, thus affording instant security for unpacked sheets of bromide paper. To the bottom of the box is hinged externally a glazed frame behind which the bromide paper can be pressed flat, and in which it is quickly centred by the squares into which the bottom of the box is marked out. The box thus serves the purpose of an easel when enlarging or copying. It stands by itself, and is capable of accommodating any original up to 20 x 16 in. size. It is well made in brown polished wood at the price of 15s. 6d.

The latest hand-camera pattern of the "Antinous" release is sent

as by Messrs. W. Watson, 313, High Holborn, London, W.C. special feature is the "petal" attachment, by which it can be adapted to practically all the patterns of diaphragm shutters by merely shortening (if necessary) the wire plunger. The price of release is the same as that of the other patterns—viz., 2s. 6d.

## Commercial & Legal Intelligence.

COMMERCIAL Photo Company, Limited (Staveley, Westmoreland). 5 per cent debenture, dated May 21, 1906, to secure not more than £50,000, charged on the company's undertaking and property, present and future, including uncalled capital, has been registered. Issued by—Lancaster Banking Company, Limited.

### NEW COMPANIES.

PHOTOGRAPHIC Materials, Limited (London).—Issue on May 18 of £50,000 6 per cent. first mortgage debentures, part of a series created on May 24, 1906, to secure £5,000, charged on the company's undertaking and property, present and future, including uncalled capital. Total amount previously issued of same series, £4,000.

### CATALOGUES AND TRADE NOTICES.

MESSRS. NEWMAN AND GUARDIA, 90 and 92, Shaftesbury Avenue, London, W., have issued re-editions of the booklets describing their latest cameras, the N. and G. "ordinary" and "reflex" patterns, the folding cameras, "Nydia" and "Sibyl." The brochures describe the advantages of these instruments very accurately and fully.

SOME very attractive and good work in enlargements has been shown us by the firm of Jeffery, Edwards, and McLeod, 17, Eccles-Road, West Ealing, of whose productions of both the inexpensive and more costly descriptions we have formed a high opinion. The firm has worked out some good-looking Cosway effects in wide enlargements, in which class of work also it offers some attractive lines with a fancy surround on which the figure slightly roaches. It delivers sepia-toned enlargements to two standard sizes of colour, and in working up in monochrome shows itself able to meet requirements of all kinds at prices which certainly do not impress us as exorbitant.

A NEW booklet has been issued by Messrs. Houghtons, Ltd., drawing attention to the Sanderson camera. It should be in the hands of those who do not know the great capacity of this make of camera. The booklet is also a price list, and is sent free.

A NEW list of miniature cases and frames has been prepared by the Photographic Supply Company, Grosvenor Buildings, Steelhouse Lane, Birmingham. It illustrates and prices the very full line of cases of this class which the firm carries, including rims, gold and silver frames, and every description of case.

### FORTHCOMING EXHIBITIONS.

June 20: Hastings and St. L. S.A.C.—Sec., Miss Watson, Deverell Street, De Cham Avenue, St. Leonards-on-Sea.

June 27: Armagh A.A.—Sec., A. E. Craddock, 10, College Street, Armagh.

August 6: Andover and D. H.S.—Sec., W. I. Gradidge, Jubilee House, Andover.

September 14 to October 27: The Photographic Salon.—Sec., Gerald Craigie, 5a, Pall Mall East, London, S.W.

September 20 to October 27: Royal Photographic Society.—Sec., McIntosh, 66, Russell Square, Bloomsbury, London, W.C.

October 6: Bristol Photographic Club.—Sec., J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.

October 17 to 20: Rotherham Photographic Society.—Sec., H. C. Hemmingway, Tooker Road, Rotherham.

November 16 to 21: Southsea Camera Club.—Hon. Sec., F. S. Hoyte, "Lismore," Stafford Road, Southsea.

November 20: Sefton Park Photographic Society.—Sec., A. W. Parr, 34, London Grove, Liverpool, S.

November 27 to 30: Hove Camera Club.—Hon. Sec., W. H. Bone, 32, Sackville Road, Hove.

December 11 to 15: Southampton Camera Club.—Hon. Sec., S. G. Kimber, "Oakdene," Highfield, Southampton.

1907.

February 12 to 23: Sheffield Photographic Society.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge.

March 14 to 23: Leicester Photographic Society.—Sec., W. Murray, 60, Melton Road, Leicester.

April 29 to May 14: Photographic Society of Ireland.—Sec., R. Benson, 35, Molesworth Street, Dublin.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held June 12, the President, Major-General Waterhouse, in the chair. Mr. C. P. Butler exhibited some specimens of colour-photography sent him by M. Graby, which were said to have been made at one printing from an ordinary negative coloured to imitate the colours of the original subject. Mr. Butler had no information as to the *modus operandi* of the process, which he believed was a secret one, and would be shortly placed on the market in France.

A paper on "The Picturesque in Landscape," by Mr. Horace Mummery, was then read by the author. Mr. Mummery commenced by considering the place of landscape in art from the historical standpoint, and contrasted the attitude of the Greek sculptors to the beauty of natural scenes with that of present-day artists. It was not until the middle of the seventeenth century, he said, that really great landscape works were painted. He then traced the progress of landscape art from its commencement in realism down to the modern cult of impressionism, instancing the career of Turner, which showed at various stages this same process to impressionism. Impressionism led Mr. Mummery to talk of the relation of photography to art and the place of photography in art, and it was difficult from this point to follow the author's treatment of his nominated theme. His severe criticism of the failings of photographers, particularly in imitating the style of other forms of artistic expression, proved, however, no less interesting than the subject at the head of his paper, and

provoked an animated discussion, in which the Rev. F. C. Lambert, Messrs. H. Snowden Ward, E. T. Holding, P. Bale Rider, J. C. S. Mummery, and the chairman took part.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting held on Thursday, June 7, 1906, Mr. A. Haddon in the chair, Mr. A. W. Green (of John J. Griffin and Sons, Ltd.), lectured upon "Self-Toning Paper and the Principle Underlying Its Action." Referring more particularly to "Goldona," he said:—

"It is curious that very little has been written or said as to the principle underlying so-called self-toning papers. As far as I have been able to trace, not one of our chemists has ventured to make a statement as to the action which takes place during the simultaneous process of toning and fixing the print. The explanation may be that, the introduction of self-toning papers being comparatively recent, time has not sufficed to permit of full investigation. In any event, it cannot be gainsaid that self-toning papers are becoming very largely used, and for various reasons are likely to replace to a considerable extent ordinary P.O.P.

In giving this subject consideration permit me to sum up briefly the advantages and disadvantages of self-toning papers.

(1) There is the advantage of simplicity and of time and labour saving. Instead of having to prepare for each batch of prints a toning bath, this is done away with altogether. All that is absolutely necessary indeed, is to plunge the prints in a solution of plain hypo for a requisite period, and then wash.

(2) There is the advantage of an entire absence of double-tones—the old bugbear of P.O.P. printing.

(3) We have the advantage of reliability, the colour of the print being determined at the final stage and subject to no modification by an after process, as is the case with the separate toning and fixing of P.O.P.

With respect to the other aspect—as far as can be seen there is only one disadvantage, and that, as I hope to show you, only a questionable one: I refer to the undoubted fact that certain prints made on certain brands of self-toning papers have been found to fade. Why this is no one at present has clearly explained, but the opinion that prints on self-toning papers do occasionally fade has been gradually gaining ground for some time past.

Now this fading may be due to several causes. It may be explained by insufficient fixation. A considerable proportion of self-toning papers tone so rapidly in the hypo that the temptation to remove them before they are completely fixed is too strong to be resisted. In fact, with some papers there is no alternative, if a warm tone is desired, but to remove the print at an early stage and take the risk of fading. With a combined toning-fixing bath the prints may be removed to a plain hypo solution to complete the fixation, but this is, of course, not possible with a self-toning paper. There is no doubt in my mind that insufficient fixing explains a good 50 per cent. of faded prints on self-toning papers.

Then there is the very common error of insufficient washing after fixing. It cannot be too frequently stated that the procedure of putting a number of prints in a small dish and allowing water to trickle down on the back of the top print, must inevitably lead to faded results. The prints must be in a vessel large enough to permit free circulation of water between them; they must therefore be agitated either by the force of the water or by mechanical means.

Lastly, there is the use of an exhausted hypo bath—the danger here being two-fold. If any silver chloride is allowed to remain in the paper, change of colour must of course ensue, but in addition to this, there is the greater probability of sulphurisation, owing to the decomposed state of the bath. Hypo is very cheap, and a fresh bath should be used for each batch of prints, and sufficient hypo solution should be employed to well cover the prints. It is not wise to use too much solution, however, as a certain amount of gold appears to be dissolved out of the paper, and hence for toning purposes there should not be a large excess of solution.

Now, all these causes of fading are connected with manipulation and are not directly connected with self-toning, nor are they the result of placing prints containing gold in hypo only. The question there-

fore arises—are there any contributory causes of fading due to self-toning process *per se*? A careful study of this question compels one to answer, "It depends on the composition of the emulsion the paper used." If the paper is coated with a complicated emulsion containing a considerable quantity of substances which are readily soluble in hypo solution—particularly free acids—then there is no doubt that there will ensue complicated chemical reactions, and these will be more than likely contributory causes of fading. supposing you have an emulsion of such a simple nature that the print there is very little else which need be taken into account beyond reduced silver and unreduced silver chloride—that is to say, the silver acted on by light and the silver chloride which has been protected from light—then upon one condition, there is no apparent contributory cause to fading that can be discovered.

This condition is that there should be such a defined quantity of gold in the paper that it will exert a preponderating influence in the toning action. This, perhaps, is the most important item in connection, for not only does it affect the permanence of the print, but largely determines the quality, richness, and purity of tone of the same.

In the articles published by Messrs. Haddon and Grundy on toning prints in a mixture of hypo and gold, the following very terse statement is made:—"Prints toned in a bath giving a large deposit of gold have a much better chance of being lasting." These experimenters also found that when gold was present in fair quantities sulphur toning was, so to speak, discouraged and made tacitly impossible. They proved that prints not previously washed, lasted better when toned in hypo and gold than when simply fixed in hypo. It is these broad principles, and to meet the requirements I have suggested that the new self-toning paper, "Goldona," has been manufactured.

"Goldona" contains as few chemicals as is possible consistent with the turning out of a high-grade emulsion. It contains a minimum of acid, and in addition there is embodied in the emulsion an adequate quantity of pure gold salts. As a consequence, prints, fixed only, should be sufficiently lasting for all practical purposes, and prints, washed first, should be as permanent as any P.O.P. can be.

As to the chemical action of the self-toning process it may be assumed that the action of daylight on "Goldona" paper is twofold. It reduces the chloride of silver to subchloride, liberating chlorine, and it reduces the gold salts also to sub-chloride.

Now, what happens when the print is placed in the hypo bath? With a complicated emulsion all sorts of reactions take place which it is quite impossible to trace, but with a simple emulsion such as is used for "Goldona," there is a reasonable possibility of hitting upon the chemical progress of the toning. Firstly, then, the altered silver chloride is dissolved (with any other free or organic compounds of silver), the print changing in consequence to a yellow colour. Next, after a lapse of a few minutes, the sub-chlorides of silver attack the sub-chlorides of gold, and extracting the chlorine from silver chloride, which as soon as so converted dissolves promptly in the hypo solution. This action continues step by step until finally in from ten to thirty minutes the whole of the gold and remaining sub-chlorides are reduced to the metallic state leaving an image consisting of a combination of gold and silver in a very fine state of division. What about the dissolved silver chlorides and their decomposition products? Do these affect the toning action? It is probable that only after the gold chloride has been reduced does the sulphur toning action commence, accompanied by loss of brilliancy and reduction of the high-lights.

Certain peculiarities in the manipulation of "Goldona" substantiate this argument. The prints are found to tone equally well whether washed before toning or not, thus seeming to demonstrate that the assistance of the sulphides are not necessary. The toning action is not unduly rapid as is the case, for instance, with papers containing acids or other chemicals likely to accelerate toning, and the resulting prints have that rich and pure appearance which is not to be mistaken for any other tone except gold. Indeed, this somewhat leisurely toning action is one of the most important advantages which can be claimed for "Goldona." Warm tones can be obtained without imperilling the safety of the print by incomplete fixation. Furthermore, the toning is more even, more under control, and the results probably finer.

Printing is done in the usual manner. For warm brown and

chocolate tones, the prints need be only very slightly darker than they are required to be when finished. In fact, "Goldona" does not lose much in depth in the fixing. For the colder tones, however, where somewhat prolonged fixation is necessary, there is more reduction, and in that case the best results are obtained by over-printing.

The fixing bath, which in the case of self-toning papers might be best described as the "reducing" bath, should vary in strength according to the tone required.

For very warm tones—red sepias—not the chocolates—use

Hypo (crystal) .....	2 ozs.
Water .....	10 ozs.

In this solution the prints are plunged one after the other and kept moving for at least ten minutes. It will usually be found that fifteen minutes immersion is necessary to secure a pleasing warm tone. If you are keen after permanency throw the hypo bath away after use. If you are not very particular on this point you will find that a used hypo bath will tone rather better, because a certain amount of gold—not very much—has dissolved in the hypo solution, and this helps the toning action.

For a good rich chocolate and tones approaching purple use the stronger bath:—

Hypo .....	4 ozs.
Water .....	10 ozs.

This strength seems to be the best on the whole, and certainly complete fixation is more certain.

After reduction or fixing the prints are transferred to a proper washing apparatus, and kept well moving in running water for three-quarters of an hour to one hour.

During the discussion which followed Mr. Green's remarks, and the toning of some prints, Mr. Teape asked what difference in time the washing of the prints prior to the toning made when a certain tone was required? The reply was that the difference was one of a few minutes only.

Mr. A. L. Henderson remarked that self-toning papers to his knowledge went back fifty-one years, and asked should the hypo be natural, acid, or alkaline, because if one state of the bath was right the others would certainly be wrong. Mr. Green replied that the hypo used by him was the ordinary commercial hypo crystals, and so far as his experience went the baths being either acid or alkaline did not seem to matter much.

Messrs. Freshwater, Teape and Human passed round prints upon the paper. Mr. Teape remarked that he had tried to obtain the same tone upon a print cut in two, one-half being washed and the other not; he had however failed. The Chairman said that he had made prints in the same manner, and the tone was so near that one could not detect the difference. Mr. Teape observed that he made both alkaline by the aid of soda carbonate, and this was generally thought to be the cause of his failures.

Referring to the permanency of the print, Mr. Human asked whether in the case of the print that had been exposed to light for three months, it would not have been a better test to have covered part of the prints with some opaque material, because if the print had changed at all the change was in this case all over, and it was to his mind no test at all. Mr. Green said that the suggestion was a good one, and he would carry it out and report later.

Mr. Haddon, in proposing a vote of thanks, said that from his experiments "Goldona" had come to stay, and any paper that would stand the tests of the L. and P. members as the paper had done, would certainly stand before any society.

EDINBURGH PHOTOGRAPHIC SOCIETY.—The forty-sixth annual meeting of the Edinburgh Photographic Society was held last week in 36, Castle Street.—Mr. J. T. Cundall (president) in the chair. The annual report by the Council stated that the membership at present was 429. Last summer new dark and enlarging rooms were fitted up at a cost of £200, making the premises as up to date and convenient as any in the country. The art union promoted in connection with the Society's exhibition was slightly more successful financially than that of the previous session. A sum of £24 8s. 6d. was expended in the purchase of pictures exhibited. The work of the survey section continued to make progress. The report was accepted. Office-bearers were elected for the session. Mr. Andrew H. Baird, F.R.P.S., was appointed president.

## Correspondence.

### URANIUM-TONED IMAGES.

To the Editors.

Gentlemen,—Mr. Wall's letter on this subject and his slides are very interesting, and seem to prove that differences in the formulae do affect the colour, independently of such variations as may be due to incomplete action. It has, however, been my experience that the colour varies slightly with the character of the image, and it would be interesting to compare the results obtained by cutting a slide such as A in half, and treating the two portions separately. There should be a difference, but it might not be so great as at present. Slide C is very curious, as the image seems to be somewhat of the character of D. I should say that Mr. Wall's explanation is the correct one, as I know the toning solution is very rapidly exhausted; in fact I took advantage of this quick exhaustion in toning bromide prints, using an extremely weak solution that could not carry the process further than I wished it to go. The strength of my solution for brown tones was 1 part each of uranium nitrate and ferricyanide in 3,000 parts of water. This speedily became exhausted and practically colourless, and I then replaced it with fresh, so that the process of toning was carried on step by step, and stopped when the desired effect was reached. I adopted this slow process because I found that it was the only way to secure uniform action. A stronger solution attacked the light details and turned them red before the shadows had been sufficiently affected. The colours obtained in this manner were pure browns, not red-browns of the type of Mr. Wall's slide B, but deep sepias without a suspicion of red. Later, I found a better and surer way of arriving at similar results, which improved method, I believe, was adopted by others with success. In this method the print was first placed in a strong toning bath and toned to a deep full red. It was then washed, placed in weak ammonia until the toning had entirely disappeared, and afterwards retoned in the weak bath. The process was quicker than the other, and more satisfactory in all ways. I think that in both these methods the deep brown obtained is a mixed colour, due to the red-brown uranium deposit and the black silver.

Mr. Wall's slide D shows just the kind of red-stain I mentioned, but I think the solution must have contained other ingredients. I experimented at one time with baths containing sulphocyanide, and used them a great deal, but I never found one that would keep, even in the acid state. Perhaps I used the wrong acid. The bought solutions smelt like very strong solutions of cyanide, and while this may have been due to acid I always suspected the addition of cyanide.

With regard to the bad reputation of uranium toning, I have for many years been watching and experimenting with old prints with a view to overcoming the defects, if possible. One alteration is the gradual deepening of red toned prints. These become a brownish red in course of time, but the change is quite uniform and in no way detrimental. In fact, I like the softened effect. A defect much talked of is called fading; but I do not know what is meant, as I have never seen the slightest indication of fading in a toned print. The great trouble is a curious grey metallic sheen that appears in the deeper tones. This is often credited to damp and noxious vapour, but I found most unmistakable evidence to the effect that strong light is the prime cause. I also found a cure for the defect and a preventative. The cure is simple india rubber. A sharp-pointed piece of hard pure vulcanised rubber will remove the deposit completely, and a coat of celluloid varnish will prevent its reappearance. It is worth note that this varnish has no visible effect whatever upon the print. It does not give the slightest gloss, and if half a print is varnished it is quite impossible to tell the difference between the two halves when the varnish is dry. I consider its use most advisable with all bromide prints, toned or otherwise. I generally carry

it over the print and a little way over the mount to seal the print margins.

In proof of the efficacy of these methods, I have some prints about fifteen years old that are now in perfect condition, though hanging in a strongly lighted south room. A few years ago I was on the point of destroying them, as their condition was so bad, but the restoration was perfect, and there is not a spot on one of them at the present time. I have not tried the varnish on a new print, but it seems to me that it should be as effective as on a cleaned one. I remember that the late Mr. A. R. Dresser varnished some of his prints with either white-hard or copal varnish. He aimed at a good gloss, not at protection; but it would be interesting to know how these prints have fared.

Reverting once more to the question of colour, it appears to me that while the work of Atterberg, confirmed by L. P. Clerc, proves that colour varies with the formulae, yet the variations so obtained are too slight to be of much value. Moreover, I am disposed to doubt the permanency of the difference, as red toned prints invariably turn brown. For practical work I think it best to rely mainly on partial toning to secure good browns and complete toning with removal of silver by a solvent to secure red. The differences thus obtained are very marked and permanent, for though the red softens it never approaches the deep brown.

I find that Mr. Wall's slide D is cracked across the centre; I trust he does not place any value upon it for exhibition purposes.—Yours, etc.,

C. WELBORNE PIPER.

### THE STATE OF WINCHESTER CATHEDRAL.

To the Editors.

Gentlemen,—One of the most remarkable things in connection with the Photographic Convention has always been the number of non-members, who—doubtless actuated by the best motives—have from time to time been good enough to make suggestions in connection with its management and arrangements.

If you do not think sufficient of your valuable space has already been occupied by those who have written with regard to what is, and what is not photographable at Winchester, will you kindly allow me a few words to allay their anxiety?

We fully appreciate their good intentions, but I can assure them we are in very good hands; we know exactly what is possible, and (unless something very unexpected happens) we shall be able to offer our members quite six times as much photographic work as they can possibly get through in the time at their disposal. Your correspondents, therefore, need not worry any more on our account.

I should like to add that although a visit to a cathedral is always interesting, it is not the only, or, to many, the most attractive item in our Southampton programme.—Yours truly,

East Lodge, Dalston Lane, F. A. BRIDGE.  
London, N.E., June 9, 1906.

### PHOTOGRAPHIC VARNISHES.

To the Editors.

Gentlemen,—In the Editorial on the above subject, in your issue of June 8, the following statement is made concerning dammar varnish:—"We are not quite sure that it is still an article of commerce." It may be of service to some of your readers to know that dammar varnish is stocked by Messrs. Baird and Tatlock, of 14, Cross Street, Hatton Garden. It is listed at 3d. per ounce, or 3s. per pound.—Yours faithfully,

DOUGLAS CARNEGIE.

### FOCUSsing SCALES.

To the Editors.

Gentlemen,—I do not quite understand why the distances from the infinity mark on the index plate of a camera are usually assumed to vary proportionately to the distances of the object, as stated on p. 422. Being away from home I have no facilities for calculating, but, taking a simple case of a 10-inch focus lens, focussed on an object 5 feet distant, I think the camera extension will be 12 inches, the distance between the infinity and 5 feet marks being 2 inches. Now if the camera be opened 1 inch beyond the infinity mark, I should expect to find an object at 9ft. 2in. focus (not one

at 10 feet). Similarly, an object at 17ft. 6in., with  $\frac{1}{2}$ -in. opened and one at 34ft. 2in., with  $\frac{1}{2}$ -in. opened, as against 20 and 40 feet as usually assumed.

I use the equation  $f-p = \frac{p^2}{F-p}$  based on the principle that  $\frac{1}{p} = \frac{1}{F} + \frac{1}{f}$  where  $p$  = the principal focus, and  $F$  and  $f$  the conjugate foci.

If I am wrong in my figures I shall be glad to be corrected, and informed how the usual method is arrived at.—Yours faithfully,

J. A. C. BRANFILL.

Hillside, Worle, Weston-super-Mare.

June 5, 1906.

[The divisions on the focussing scale measured, from the infinity mark are inversely proportional to the distances of the object measured from the front principal focus of the lens. Mr. Branfill figures represent distances of the object from the front node of the lens, and if he subtracts a focal length from each one he will find that the rule is observed. Focussing scales are very often divided in accordance with the rule of inverse proportion, but it is to be feared that they are not infrequently marked wrongly, just in the way that Mr. Branfill assumed we intended to describe. The discrepancy of one focal length is not of much importance with short focus lenses or long distances, but it may lead to serious error with a long focus lens and a short distance. It is best to mark the distances from the front principal focus, and it would be very desirable if camera makers would agree to observe this system. As pointed out in our article, the distances marked by the diagrammatic method are all measured from the principal focus, not from the node. By adding a focal length they can be converted into nodal distances, but there is no particular advantage in doing this.—EDS. B.J.P.]

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—Will you kindly allow me space to announce that the office of the Association is now removed to 89, Albany Street, London, N.W., where all communications to the P.P.A. should be addressed.—I am, etc.,

ALEXANDER MACKIE,  
Hon. Secretary.

### A NOTE ON THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—When Mr. Driffeld published his paper on the "Control of the Development Factor and a Note on Speed Determination," P.J., Vol. XLIII., p. 17, I adopted the method therein described for determining the growth of the development factor with the time of the development. Subsequently I also took into use the tables and formulae published by Messrs. Mees and Sheppard, in their thesis, entitled "On the Sensitometry of Photographic Plates," P.J., Vol. XLIV., p. 282, for calculating the constants which determine the value of the development factor. These are the ultimate development factor  $\gamma_{\infty}$ , and the velocity constant of development  $K$ . The values, according to Mr. Driffeld, are, of course, obtained graphically, whilst they are obtained mathematically by the system introduced by Messrs. Mees and Sheppard. The results obtained by both of these methods are tabulated side by side, and for some time I have been concerned regarding the want of union between these two systems. So far as I can see, there ought to be some definite relationship between the value of the development factor, as found by experiment, and the value of  $K$ , as determined from the same factor, or rather two factors. I assume that the value of  $K$  increases according to the rapidity with which the plate may be developed, and yet my experiments fail to confirm this assumption.

In explanation of my difficulty I quote the results of a series of ten readings. In the first table I give the actual values obtained, and in the second table the plates are placed in their order of merit under the different heads.

In obtaining these results two strips of each plate were simultaneously exposed to a standard candle in the H. and D. exposing apparatus; one strip was developed for two minutes, and the other for four minutes with H. and D. standard pyro soda developer, at a temperature of 65 degrees F., in the manner advocated by Mr.

ld; from these strips the curves were plotted and the development factors obtained in the usual manner.

3.—Under this head the figure gives the necessary time of development in minutes to obtain a portrait negative.

5.—Represents the time of development in minutes to obtain a landscape negative.

—Development factor obtained with two minutes' development.

—Development factor obtained with four minutes' development.

—Velocity constant of development, calculated by Messrs. Mees and Heppard's tables.

TABLE I., giving Actual Figures.

K.	$\gamma_1$ .	$\gamma_2$ .	$\gamma_0.8$ .	$\gamma_1.3$ .
90	1.00	1.27	1.40	4.00
12	.84	1.50	1.90	3.40
137	.73	1.28	2.35	4.20
162	.73	1.28	2.35	4.20
2125	1.02	1.70	1.60	2.80
237	1.20	1.96	1.30	2.30
337	1.82	2.00	1.25	2.00
2125	1.02	1.70	1.60	2.80
162	1.05	1.82	1.60	2.70
250	1.00	1.60	1.60	3.00

TABLE II., giving the Plates placed in their Order of Merit.

	$\gamma_1$ .	$\gamma_2$ .	$\gamma_0.8$ .	$\gamma_1.3$ .
.....	7	7	7	6
.....	1	6	1	9
.....	9	5	8	5
.....	8	5	5	10
.....	5	10	9	2
.....	10	2	10	1
.....	2	3	2	3
.....	3	1	3	4
.....	4	4	4	4

Comparing these tables it is to be understood that the results of the methods under discussion are obtained from the same development factors,  $\gamma_1$  and  $\gamma_2$ . It will be noticed that whilst graphically obtained results,  $\gamma_0.8$  and  $\gamma_1.3$ , nearly coincide with those obtained by experiment, in only one case is there dissent, and it must be admitted that at the best such results are necessarily somewhat crude, yet the resulting K obtained by calculation appears to give entirely misleading figures. For instance, K 1 comes at the top of the list under K, whilst by measurement it is found to take the third place for short development, and the fourth place for long development. The only instance in which the figures K,  $\gamma_1$ ,  $\gamma_2$ , are in agreement is with the plates 5 and 8. Examples of inconsistency might also be quoted, but those who are interested will probably discover them by an examination of the tables.

It does not wish to be misunderstood. In publishing these results of the methods under discussion I desire to direct attention to a matter which only requires further explanations, to be of great service to myself and others, who are at present struggling in the outer darkness. My friends have speculated upon the possibility of an error in the equation where  $\frac{\gamma_2}{\gamma_1}$  occurs because the same dividend is obtained where  $\gamma_2 = 4 + \gamma_1 = 2$ , or  $\gamma_2 = 2 + \gamma_1 = 1$ , or  $\gamma_2 = 1 + \gamma_1 = 0.5$ , where there would be a great difference in the speed of development of these three hypothetical plates. Whilst these figures are simple, for the purpose of illustrating a principle, it will be noted that other figures might be found to give equally misleading results. It naturally follows that if the method of obtaining K be wrong the calculations for  $\gamma_0.8$  are also wrong.—Yours truly,

ARTHUR PAYNE.

A PARTNERSHIP has been arranged between Messrs. Thomas Beddard, F.R.P.S., and A. E. Dean, photographic experts, dealers, etc., proprietors of the "Craven" photographic specialties. All communications should be addressed to the office, at 4, Duke Street, St. John's, W.C. Mr. Beddard has also in preparation a lantern lecture, entitled, "The World of the Camera," to be reminiscatory, historical, popular, scientific, amusing and entertaining. Any photographic societies desirous of securing this lecture for their autumn programmes should communicate with the above address.

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

\*.\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

A. Churchward, 206, Selhurst Road, South Norwood, S.E. Four Photographs of Oil Paintings by Correggio. Saints Matthew, Mark, Luke and John.

A. Shaw, 32, Briardale Road, Seacombe, Cheshire. Photograph of the Wallasey Ferry Steamer "Iris."

A. T. Sidwell, Ivy Cottage, Meriden. Photograph of Baddesley Clinton Hall, Warwickshire.

H. S.—We do not know whether there is any positive transfer paper which will reproduce drawings in the manner indicated in Question 1, but there are two methods employed which do the same thing without the intervention of any camera method, the first being the graph method, in which a blue print is taken from the negative. This is placed on a gelatine graph, and from this can be pulled ordinary proofs in litho transfer ink, and these, as required, laid down on stone and lithographed. The second is the Vandyke process, in which a negative of fish-glue is made on the zinc plate, and then the clear lines inked up and the fish-glue negative ground dissolved. From this as many lithographic prints can be taken, or transfers pulled, as required. The answer to Question 2 is given in answer to 1. The answer to No. 3 is, No—that is, if you mean by negative, a negative made in the camera. As regards 4, it may, if a sufficient novelty, be patentable, but it is doubtful whether it would have very great material advantage over the Vandyke process, which is extremely cheap and rapid, giving results which, with skilful work, are perfect.

BROMIDE DEVELOPING.—Will you kindly enlighten me, through your paper. When developing a large batch of prints, my method is to develop one at a time (using metol-hydroquinone), then transferring to an acetic acid bath (one ounce to one pint), for a few seconds, afterwards placing in a dish of water until all are developed; I then give them three changes of water, and fix. Is this washing sufficient, or would a trace of the acid be detrimental to the fixing bath? If I do not use the acid bath the prints have a yellowish look about the whites. Would the acid bath answer equally well when developing with amidol?—SMILAX.

You are unwise, we think, to use an acid bath. It should not be necessary with either of the developers you name. If you get stain it would appear that your developer is stale or not made with sufficient sulphite. In place of an acid bath we should recommend you to put a little metabisulphite of potash in the fixing bath, but we have never found this addition necessary ourselves in bromide work. Insufficient washing after the acid will very probably give rise to yellowed lights.

LENSES FOR ENLARGING (Reply to Querist).—There is little to choose between the lenses. If used with the full aperture the latter will be slightly the quicker of the two; but the longer focus one, whichever it be, will probably cover the plate the better. Why not try the lenses and see which answers your purpose the best?

WEIGHTS AND MEASURES.—I have your valuable annual for 1906—the B.J.P. ALMANAC—but I am in difficulties as to some of the formulae, upon which I am about to ask you, if you will kindly enlighten me. Those I refer to are on pages 814 and 815, which

I am wanting to make use of, but cannot proceed until I get the proportions in English weights and measures. I am entirely in the dark as to (50. ccs. 1: 1000 metal solution), etc., etc., and what would be a valuable thing to me is lost until I can get the proper proportions in English measures. Your kind assistance will greatly oblige.—C. P.

You will find the equivalents of all the metric weights on pages 1087, etc., of the *ALMANAC*.

**MIDGET PORTRAITS.**—Could you explain the method of taking twelve small photographs on one plate, one exposure, and one lens?—F. Cox.

You require a repeating multiple plate. If you write to makers such as Mr. Fallowfield, Sharp and Hitchmough, or the Tress Co., you can obtain particulars of the apparatus and its method of use.

**STUDIO LENS.**—I should take it as a great favour if you could let me know of a good portrait lens to use in a studio 18ft. long. I want it for midgets and general all-round work. I am at present using a Dallmeyer's 2B portrait lens, but find no depth of focus in it for groups, and after focussing up sharp on screen I find in most cases it is entirely out of focus in the centre of figure. I have tried R.R. lens, but find they are too slow and no good for cabinet heads.

If you are using this lens for cabinet pictures, as we presume you are, we are not surprised that you cannot get all parts in focus at the same time. The "2B" is only constructed for carte pictures, though it is sometimes, when stopped down, used for cabinets. We should advise you to get an anastigmat of similar focus, with an aperture of  $f/6$ —say a Stigmatic by the same maker, or one of the many anastigmat lenses, particulars of which you will find in the "*Almanac*."

**AEROGRAPH WORK.**—Can you give me some particulars of the method of finishing bromide enlargements by the air-brush process in connection with crayon and Indian ink? What firm is the material to be got from?—T. E. H.

The only instructions published are those issued by the makers of the air-brush, the Aerograph Co., Holborn Viaduct, E.C., from whom and from artist's dealers you can get the necessary materials.

**A POINT OF PROFESSIONAL COURTESY.**—I should like to have your opinion and views on a matter which I think should be clearly understood between all professional photographers. I was engaged to photograph a wedding group, and by some misunderstanding another photographer was engaged as well. When I arrived on the scene I, of course, was surprised to see another man there, so I waited till he had done. I then stepped forward and explained matters to the bridegroom (who engaged me), and he let me have what I wanted of them. My opponent having photographed his group in the sun I picked out a much better spot, and arranged the group, when up he steps and take some more negatives. I told him it was not a very nice thing to do under the circumstances. My object in writing to you is to get your feeling on the matter.—H. B.

Evidently your confrère (if may so call him) was not over-scrupulous. We suppose he acted in good faith in attending in the first instance, but it was hardly consistent with ideas of professional dignity for him to avail himself of your selection of lighting. Yet the case is not one in which we can be of any assistance.

**RETOUCHING KNIVES.**—In the *JOURNAL* for May 11 you gave Mr. H. Stottard's lecture on "Retouching Hints," of which he advised for reducing densities, small retouching knives, costing 6d., and medical dissecting knives, both blunt and chisel-pointed. Will you kindly let me know through the medium of your paper where these knives are to be obtained, and cost of same?—J. PATERSON.

The small retouching knives are sold by all the large dealers, such as Fallowfield. For the other (surgical) knives you must apply to a surgical instrument house, such as Allen and Hanbury, Wigmore Street, W.

**STAINED NEGATIVES.**—I have two negatives which are valuable to me, particularly because I am unable to replace them, and they have recently shown yellow stains, which I fear will prove obstinate. In one case the stain is strongest at the margin of the narrow

side of the plate, and gradually it shades away towards centre. The other has a strongly-defined and very intense yellow patch, which encroaches upon the sleeve of the sitter's dress. I think the stains are due to insufficient washing after fix, but I shall be pleased to have your opinion on the matter if you can suggest a remedy in your reply.—HYPO.

There is no satisfactory method of removing such stains and restoring the negatives to their original condition. The best would be to make transparencies by contact, and then mask them out with tissue paper or coloured matt varnish, and make a set of negatives by contact. If the yellow stains print well, then the rest of the negatives it would be as well to mask original negatives with paper in this way first.

**ENQUIRER.**—Reigate, Surrey.

**HALF-PLATE.**—How can we tell you? We do not know what it cost, or will cost you, to take the photographs. If you are in business to make money you ought to be able to make calculation for yourself.

**FRENCH VIGNETTE.**—Having recently made for myself a French vignetter, is there a patent or any restriction to prevent selling them?—F. O.

We do not know the form of the apparatus you term "French vignetter." There are many kinds of vignetter arrangements in use, but there is no patent in England any one that we know of.

The model furnished bungalow cottage which Messrs. Oetzmayer have had on exhibition at their Hampstead Road establishment during May, and which they will keep available for inspection until the end of the present month, should interest photographers in showing the effective use which can be made of the reasonably priced modern furniture. Conventional furniture such as has ornamented studios for generations past has been wholly discarded by many proprietors alive to the wisdom of making the studio refreshing and different from the familiar apartment which many sitters enter with apprehension. The secret of much successful work has doubtless been, in the first place, the decoration and furnishing of the studio in such a way that it did not in the least suggest its real object. The paraphernalia has been kept in the background, and the sitters feel as though he was entering an ordinary room. Much more might be achieved in this direction by a study of schemes of furnishing embodied in the creations of the modern large furnishing houses.

**A CAMERA Ordered Out of Court.**—An amusing encounter between a photographer and Justices Grantham and Lawrance occurred during the resumed hearing of the Bodmin election petition of Monday last. The photographer placed a camera on a tripod under the gallery. Just as he was about to remove the cap from the lens for the exposure, Mr. Justice Lawrance became aware of the operations in progress with the camera, and, while holding out his hand before his face, his lordship nudged his brother judge. Mr. Justice Grantham instantly requested the unwelcome intruder to desist. Their lordships' action may have been due in part to the conduct of a photographer at the first trial, who not only secured a photograph of the Court during a sitting, but reduced it to a picture postcard. Yielding to pressure later on, he withdrew the card from circulation.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Salon of the Paris Photo-Club opened last week at the Palais place in the Champs Elysées. A review of the exhibition by Robert Demachy appears on page 486.

new form of assistant's certificate has been drawn up by the Professional Photographers' Association. (P. 482.)

dispute the correctness of a recently published opinion of the City of copyright in duplicate subjects. (P. 482.)

Pirie Macdonald, of New York, in a Convention address on photographic Ethics," urged a higher standard of professional duty. (P. 487.)

nts on keeping the studio cool and on giving it the appearance of coolness appear on page 491.

posure in Pinhole Photography.—Mr. Douglas Carnegie finds experiments that the law of inverse squares does not hold in plate work, and that the correct exposure is always greater than calculated from relative aperture ratios. (P. 484.)

lour-Photography.—The specification of Dr. J. H. Smith's one method of colour-photography, in which a geometrical three-r screen is used, has been published. Roll-film and printing- are the subjects of other recent patents. (P. 494.)

lour-Photography.—Baron von Hübl concludes from a discussion of colour mixtures that the Young-Helmholtz theory of colour vision is of no importance in three-colour photography. (P. 489.)

business Depression.—Attention is drawn to recent suggestions of reviving business. (P. 484.)

possible source of error in photometric readings has been indicated. (P. 485.)

other commercial gum-bichromate paper, shortly to appear on market, was demonstrated before the Croydon Camera Club last week. (P. 496.)

## EX CATHEDRA.

### The Convention President's "At Home."

Our readers interested in the Convention will have noted that on the Wednesday afternoon (July 11) the President was announced to give a yachting party "At Home," for which a special programme would be issued. We are now in a position to state that the "Duchess of Kent"—one of the largest steamers on the Solent—has been chartered for this occasion, and will leave the Royal Pier at 2.30. The catering has been placed in reliable hands, and Herr Carl Heubert's celebrated Viennese Band will accompany the party. This cruise on Southampton Water should prove one of the most enjoyable items in the Convention programme.

\* \* \*

### A Postcard in Half-tone.

As a commentary on the advice we have given to photographers recently that they should seize the opportunity of producing picture postcards of local interest, we may quote the experience of a reader, Mr. F. Holmes, of Mere, in Wiltshire, a professional photographer and member of the Professional Photographers' Association. During a recent heavy thunderstorm a month ago he took a negative of Mere showing a vivid flash of lightning descending from the zenith alongside the church tower. This photograph, after registration of the copyright, was reproduced in half-tone, and placed on the market, with the very satisfactory result, so Mr. Holmes tells us, that twenty thousand were sold in fifteen days, a number which is startling, even when one bears in mind the astonishingly large editions of picture postcards. As the name of the photographer appears on each of the cards, Mr. Holmes may congratulate himself on the wide publicity which he thus secures, in addition to the round sum which he may be presumed to have netted on the sale of the cards.

\* \* \*

### The Latest Note in Modern Furnishing.

The opening of the new house of Waring and Gillow in Oxford-street last week was an event of the day, not only from the magnificence of the premises and their contents of furniture, but from the brilliant success which attended Messrs. Waring's scheme of making the vast establishment a show-place for a week, where visitors might call and inspect, but were invited to defer their purchasing to another time. As a result of this simple idea, the great block in Oxford-street was filled from morning to night with a congested stream of humanity, chiefly feminine, and bent upon the study of things domestic. Yet the chief interest to a photographer is the scope which such an establishment as the new Waring's gives him in the furnishing of the rooms in which he receives his customers. The manner in which the halls and galleries of the firm are

arranged is in itself a model of what the photographer may aim at in his own less ambitious schemes of decoration.

### Focal Length of Studio Lenses.

\* \* \*

There is a tendency nowadays for the professional worker who has been largely self-taught as to his photography to pay too little attention to the matter of focal length in the selection of lenses for studio work. Quite recently we have had several inquiries on the choice of an objective, and in a number of cases the lens suggested has been quite unsuitable, owing to its shortness of focus. In one case a lens was wanted for whole plates, possibly groups, and for three-quarter length cabinets, the length of the studio being only 12ft.; in another it was only possible to get 8ft. 6in. from the sitter, yet full-length cabinets were being attempted. A lens of 6in. focus failed to give the whole of the figure, and we were asked to suggest a lens of shorter focus which would cover the plate and include the whole of the subject. The perspective in a full-length cabinet taken with a 6in. lens would be exceedingly violent, the nearer portions appearing on too large a scale, and the line of the floor running up very badly. What the effect would be with, say, a 4½in. lens may be imagined when we say that for good perspective in full-length pictures a lens of at least 10in. focal length should be employed. It may be argued that with a short studio there is no alternative but to use a short-focus lens, and this is true to a certain extent. But the limit is reached long before one gets to a 6in. lens for any cabinet-sized portrait. Any worker who hopes to hold his own among his competitors must recognise that he should wait till he gets a longer studio before opening, or he should confine his attention to work which may be done with less chances of complete failure than is the case with the type of portrait to which we have referred.

### Assistant's Certificate's.

\* \* \*

After being before the public for more than a year, the scheme of certification drafted by the Professional Photographers' Association has met with little or no response from the class which it was designed to benefit. It was realised and admitted that the scheme had several serious obstacles in the way of its accomplishment, but the Association apparently under-estimated the effect of these obstacles, and manifested too high a degree of solicitude for the more specialised photographic assistant. That type of assistant which forms a large proportion of the rank and file of the wage-earners in photography, namely, the man who can operate, retouch, print, and turn his hand to other branches of the business, was unprovided for. In many trades or professions this character of the scheme would have been the very one to have assured it success, from the incentive it held out for workers to obtain recognition of their skill in some particular branch. But experience has shown that the majority of the "all-round" assistants lack the requisite pride and ambition in their work which should lead them to take such a step for their self-advancement. As a result, the original scheme of certification has been withdrawn—to be brought forward again, we hope, when there are signs of conditions favourable to it—and in place of it a "registration certificate" has been drafted, the object of which is much less ambitious, but one, nevertheless, which should be of immense usefulness to both employers and employed. To state the nature of the "registration certificate" in a few words, it is an endorsement by the P.P.A. of the qualifications of the assistant, as claimed by him, by reference to his present and previous employers. The scheme thus provides the assistant with a document which states the assistant's claims as to

himself, with the names of the firms in whose establishments his work has been done. The scheme, as we have said, is not an ambitious one, but appears to possess a capacity for usefulness which should draw to it the support of both the classes whom it concerns.

### A New "Photo-Copy" Process.

\* \* \*

Improvements continue to be made in the so-called "blue" or "heliographic" photographic printing processes by which engineers and others are accustomed to reproduce or have reproduced their drawings and tracings. This branch of photography, though little known amongst ordinary photographers, commands a considerable custom, particularly in the North of England, where factories and engineering works require large numbers of copies of working drawings for the use of mechanics. The old ferro-prussiate process has been almost supplanted by the more rapid "black-line" and "sepia" papers, and these in turn are in process of expulsion by processes which will give a bold black carbon line, and by others, which will also permit of twenty or thirty copies being obtained for one exposure to light. The latest addition to these methods is the invention of Mr. Henry Shawcross, to whom the introduction of the black-line and sepia processes was originally due. His latest process, so we gather from a circular issued by Mr. Shawcross, is based on the ferro-prussiate, in that a single operation is necessary, but the copy is obtained in line of Indian ink, embedded in the fibre of the paper. In addition, the process allows the engineer himself or his unskilled assistant to produce a litho transfer, from which copies can be taken off true to scale. A number of such processes have been advanced of late, but none, so far as we know, which answers to the description of this one. The best known is the so-called "Vandyke," which visitors to the Convention will, perhaps, have the opportunity of seeing at the Ordnance Survey Office. Of the processes on the graph principle, that introduced by Messrs. B. J. Hall will be remembered. A short note on it appeared in our issue of March 30 last.

### Copyright in Duplicate Subjects.

\* \* \*

A recent answer to a correspondent of a contemporary raises a point in copyright law which is highly debatable, and shows how impossible it is to frame an Act of Parliament which shall provide for every emergency. The inquirer asks if he may photograph an arrangement of still life, part with the copyright in his representation, and photograph the subject again to acquire a new copyright in what is virtually a facsimile of the previous photograph. Our contemporary assures him that he can, basing his reply upon a literal interpretation of that clause of the Copyright Act, which states, the "right of any person to copy or use any work in which there shall be no copyright, and to represent any scene or object, notwithstanding that there may be copyright in some representation of such scene or object." This clause, it is true, will bear the interpretation which is thus put upon it, but does anybody suppose that such a practice as that which our contemporary suggests as legal—we will say nothing of the morality of the act—is likely to be sustained in a court of law. As we read it, the clause was inserted in the Act to protect artists and photographers in their selection of a particular view point for a photograph or painting, or in copying some painting or work of art which might also be copied by somebody else. It was never intended, in our judgment, for the justification of persons who may practice what is nothing less than fraud by producing several independent but identical photographs, the copyright of each of which they may offer in different quarters. There has never, to our knowledge, been a case of this kind in the

parts, but should one come up there is little doubt of way in which it would be treated. The creation of copyrights *ad infinitum*, each one as like any of the others two pins, was obviously never intended by the Act. An ample will bring home more forcibly the inconsistency twisting the Act into meaning something it does not. A photographer returns home from Lhasa with identical negatives of certain of the scenery of that little-visited place. Is it likely that he can sustain separate copyrights in photographs which are identical in practically every respect, and require the production of the negatives to prove that they are, in fact, the results of separate exposures? Such an instance, which might be cited in many different forms, is a veritable *reductio ad absurdum* of the interpretation of the Act.

**Photometry.** In a paper by J. S. Dow, read at the Physical Society on May 25, the author points out that differences in the readings are found as the distance of the eye from the photometer screen is altered. We have often suspected this to be the case, and have noticed that different persons take up very different positions when making a reading, while individuals often neglect the precaution of preserving a uniform distance. With several kinds of photometer there is no viewing tube, nor anything to induce the observer to take up any fixed point of view, so, if Mr. Dow's idea is as correct as we believe it to be, discordant readings are easily produced. Mr. Dow considers that the size of the field and the order of the illumination should also be specified if different readings are to be compared, but as the name of the photometer, together with the description of light used, is very commonly mentioned, these points are perhaps of less importance than the other. We have, however, noticed that in photometers that can be adjusted either with one eye or with monocular vision often gives a different result to the other, while we have often suspected a difference between the results obtained by using either the right or the left eye alone. As photometry is very tiring work, there is a great temptation to occasionally relieve the eye by employing the other, but we feel pretty certain that this leads to inconclusive results. Possibly the best method is to use one eye throughout at a fixed distance, to facilitate this some kind of viewing tube or eyepiece is certainly desirable. Fatigue is, perhaps, most easily avoided by taking the readings rapidly and with prompt decision. In our experience hesitation and anxious deliberation not only fatigue the eye, but actually favour inaccuracy. Mr. Dow's observations concern more particularly the comparison of coloured lights, but as colour differences also exist (sometimes to a most troublesome extent) when simple densities are being measured, we think it advisable to observe the same precautions in all cases.

#### Swing back and distortion.

One of the frequent complaints which meet the portrait photographer in his work is that "the hands are so large." There are two things which contribute to this effect—in many instances, both operating together. It is well known that where a lens of short focus is employed the objects on the edges of the plate are represented on a larger scale, or, perhaps, more correctly, are lengthened out radially. This is very noticeable in the case of groups, the faces on the edges being often broadened till the distortion is almost ludicrous. In portraits where the hands come near the faces, as in three-quarter lengths, the same effect may be seen. But a more frequent cause is the adoption of an unsuitable position, the hands being considerably nearer the camera than the face. The shorter the focal length of the lens the more important is it to pose the sitter as

much in one plane as possible. A far too common practice is to neglect this point and then to get the hands into focus by using the swing-back. Although this method gives sharpness instead of blur, the scale of the hands is materially increased, as the rays forming the image travel a greater distance before reaching the focussing screen, and consequently diverge more. The aim should be to use as long a focus lens as possible, to pose the figure so that the hands do not approach nearer to the lens than the face, and, wherever it is practicable, to keep the plate at right angles to the axis of the lens.

#### BUSINESS TOPICS.

THE papers read at the recent conference of the Professional Photographers' Society of New York, reports of which have appeared in our columns during the past few weeks, should be interesting reading to many portraitists in this country, particularly to those who are at the present time complaining that with them business is by no means good. From these papers some of the more enterprising of them may possibly see a way to improve business by adopting some one or other of the American business methods, or some adaptation of them to their own conditions. There is, we think, very little question that the American portraitists are, as a rule, better business men than a large proportion of professional photographers in this country, more especially those who may be termed the middle-class men. It is the latter, we believe, who, at the present time, are complaining most that trade is bad, and it is to them that we particularly commend what was said at the New York conference. By taking a leaf out of the book of some of their American *confrères* they may possibly see a way of giving a fillip to their own businesses instead of going on in the old "jog-trot" style of twenty or thirty years ago, when business did not require so much "fetching" as it does nowadays. There is one thing that is noteworthy with regard to the American meeting—namely, that there seems to be a greater degree of good fellowship reigning amongst professionals generally in the States than there is here. The Professional Photographers' Association of this country, however, is doing much to break down professional jealousy and reserve.

To pass to one or two of the subjects dealt with at the New York meeting, it will be seen from the reports that far more attention is paid to the elements of photographic business in America than is the case in this country. Here one is continually hearing that competition is so very keen, but we gather that it is equally as keen throughout the States. But there are two forms of competition—that of price and that of quality. The former only is usually classed as such in this country. But the latter seems to be better recognised in the States than here, and is healthy competition. There is no question that the public generally do appreciate good work, even if they have to pay a somewhat higher price for it. We know of some houses that are turning out really good ordinary everyday portraits at three for half-a-crown, while for the same kind of picture the middle-class man—as we may term him—charges something like double the price. If the latter were to improve his work artistically, as well as technically, he could successfully compete with his rival, even with his higher prices. It costs no more for material to produce a high-class picture than a mediocre one, and in all the papers read at the American conference stress was laid on the point that improving the work was the most successful means of improving the business. In the States there seems to be a great tendency to raise prices by putting a higher priced picture of correspondingly higher merit

before the public, and this, according to several speakers, had proved very successful. In some instances the prices had been doubled and even quadrupled with success. Here the trend is too often to lower them.

One thing that was specially dwelt upon at the conference—and it is one that is often overlooked here—is the necessity of a good business lady in the reception-room. We here quote what one speaker said, but the same views were expressed by several leading photographers:—"We have all found in our experience that prospective customers are not always decided as to what they want, and yet they are willing to spend a little money. Therefore, the next important thing to do is to employ the services of a good receptionist. To sell pictures is a born tact, and not one that is easily acquired. You cannot use too much care in the selection of your receptionist, for the simple reason that, if a mistake is made in the lighting or posing of your sitter under the skylight, there is a remedy in the re-sitting; but if a mistake is made in the handling of your patrons in the reception-room, and they are allowed to leave your studio dissatisfied, there is no remedy. In view of these facts, you can readily realise that it is of vital importance to have a qualified receptionist." We have frequently been in reception-rooms and noticed the lack of business tact on the part of the one in charge, such, indeed, in some instances, as would not be tolerated for a week in an ordinary shop. Touching the same matter, another point which was raised by one speaker and is deserving of consideration is the practice of encouraging the sitter to call at the studio and examine the proofs instead of posting them to her with all their blemishes unexplained, to answer for themselves in a court without counsel and before a judge who often is lacking in the judicial faculty. A lady who will suddenly make up her mind that the photographs are no good when they reach her at her house will very likely take a quite different view of them when they are offered to her at the photographer's, and though this plan is not one which can be followed up in large towns, it is capable of application in many cases. And it has the advantage that in the hands of a photographer or his reception lady, who is clever at selling, it lends itself to the booking of orders, additional to the one first contemplated by the sitter.

Every portrait turned out of a studio, with the photographer's name upon it, being an advertisement for good or evil, according to the description of photography, should be borne in mind that a single bad picture will do more harm to a business than a score of excellent ones will do good. To this the American photographers seem to attach more value than we in this country.

Another matter which seemed to have been much dwelt upon at the meeting, and which is much neglected here, is the importance of a show-case as a means of attracting custom. Here photographers are very prone to crowd their show-cases with specimens of a heterogeneous character. Passers-by who have seen them a few times are no longer attracted by them. But if fewer specimens were shown, say, half a dozen instead of two or three dozen—and if they were changed every week or two, and care taken that the costumes of the new ones were in keeping with the season, the case would be a constant source of attraction. One of the speakers at the conference mentioned that he knew a photographer in a small country town who advertised that he would put a fresh portrait in his show-case every day, and as in the small place everybody knew everybody else, people were continually visiting the case to see what portrait was in it. It was stated that a photographer in another town posts the names of those whose portraits he has taken the previous week, and announces that the picture could be seen in the show-case. These methods naturally attracted much attention, and are said to have brought much business to the studio. Whether such a scheme would answer here will very much depend upon the ideas of the people of the locality, yet there is a decided novelty in it. One thing is certain, and that is that, where specimens are shown, a few distributed in a large show-case which are constantly being renewed, are far more attractive than a much larger number crowded into the same space and seldom changed.

In the above only a few of the business points dealt with at the New York conference have been alluded to. Photographers in this country will do well, however, to read the reports of the meetings, as some of them can scarcely fail to impart some hint or other of assistance in stirring up a stagnant business, or, perhaps, further increasing a flourishing one.

## EXPOSURE IN PINHOLE PHOTOGRAPHY.

THE question of the proper exposure to give in photographing with a pinhole is a matter which would seem to admit of as great latitude of opinion as do the vexed subjects of Tariff Reform and Bimetallism. Every doctor has his rule, but in their rules the doctors disagree sadly. Indeed, the anxious enquirer after the matter of pinhole exposures finds such a bewildering choice of rules submitted to him by the different authorities that he might be pardoned for resolving to eschew precept altogether, and trust his practice to luck or to his innate exposure sense.

It seemed to me, therefore, that a definite investigation of the subject of pinhole exposures was called for, and this article summarises the preliminary results of such an investigation. The object aimed at in undertaking this work was the establishment, if possible, of some precise and unequivocal rule which would enable the proper exposures for pinhole work to be deduced from any of the ordinary tables of exposures for lens work.

Suppose the correct exposure with a lens working at  $\frac{f}{x}$  is one second, then the correct exposure for the same lens stopped

down to  $\frac{f}{nx}$  would, of course, be  $\left(\frac{nx}{x}\right)^2$  seconds. Let us call this ratio  $\left(\frac{nx}{x}\right)$  the "aperture ratio exposure" for the smaller stop. [Henceforward the term "aperture ratio exposure" will be contracted into A.R. exposure.]

Again, suppose we have a lens working at  $\frac{f}{x}$ , for which the correct exposure is one second, and we require the equivalent exposure for a pinhole working at  $\frac{f}{nx}$ . One might be excused for hastily concluding that the equivalent exposure with the pinhole would be less than the A.R. exposure  $\left(\frac{nx}{x}\right)^2$ , for in the case of the pinhole there are neither lens thicknesses present to absorb the light nor lens surfaces to reflect it. In this connexion Abney writes:—"In calculating the exposure with pinhole, the same rule must be applied as in calculating it for lenses with different apertures in the diaphragms, though owing to the absence of all intervening glass, the pinhole method has an advantage." (Treatise on Photography, p. 277.) The

periments about to be described prove, however, that the equivalent exposure with the pinhole is always greater, and not less, than the calculated A.R. exposure. The equivalent pinhole exposure =  $m \times$  A.R. exposure — where  $m$  is greater than unity. Henceforth in this article  $m$  will be called "the pinhole factor." The pinhole used in my experiments was made by boring through thin zinc foil with a number 12 needle, using a fine razor hone for removing the burr, and finally cleaning out the hole by treatment with dilute acid. The foil was glued to a waterhouse diaphragm held in a lens mount from which the lenses had been removed. The diameter of the hole was determined by first photographing through the microscope a stage micrometer reading to thousands of an inch, replacing the micrometer by the pinhole and adjusting the stage till it was accurately focussed, and then finally photographing the hole in the same plate as had already been exposed to the micrometer. The mean diameter of the hole was .014 in.

The general method of procedure was as follows:—A sheet of white paper illuminated from both sides by Welsbach lights was placed in a vertical plane at a distance of about 2½ ft. in front of a camera provided with a Goerz double anastigmat lens (Series III.). [The position of the nodes of the lens had previously been determined, as also its effective aperture when stopped down to  $f/32$ , nominal—the only lens aperture at which comparisons with pinhole performances have as yet been made. It was when measuring this aperture that I discovered the somewhat disconcerting fact that the absolute diameter of the lens opening differs appreciably according as it is closed from higher apertures down to  $f/32$ , or opened up from lower apertures to  $f/32$ .] With the lens set at  $f/32$  the paper sheet was focussed, and then, making use of a repeating back, exposures of one, two, and three minutes were given. A preliminary experiment had shown that such exposures were well within the latitude of the plates used (Imperial special rapid), i.e., that such exposures under the conditions observed gave densities lying within the rectilinear portion of the Hurter and Driffield curve.

The distance between the node of emission of the lens and the plate was now measured, and the aperture ratio under the conditions of working was calculated from this measurement, and the known effective aperture corresponding to  $f/32$  nominal.

The lens was next replaced by the pinhole and a measurement made of the distance between the pinhole and the plane of the plate. This distance, divided into the diameter of the pinhole, gave the " $f$  number" at which the pinhole worked. The repeating back, still containing the same plate, was replaced in the camera, and two or more exposures of long duration (extending in one case to nearly five hours) were given. These pinhole exposures were in general so ordered that the densities resulting were intermediate between the extreme densities obtained with the lens exposures.

The plate was then developed, and the densities of the patches were measured in a Simmance Abady flicker photometer, very kindly placed at my disposal by Mr. W. Shortt, of the London and South-Western Railway Company. The density readings were in all cases mean results derived from wonderfully concordant readings of the photometer taken by three independent observers.

The method of utilising the results so obtained is illustrated by the following example:—

Lens at $\frac{1}{46.3}$		Pinhole at $\frac{1}{417}$	
R. A. Exposure = $\left(\frac{417}{46.3}\right)^2 = 81$ .		Exposure in minutes.	Density.
Lens...	...	1	...
Lens...	...	2	...
Lens...	...	3	...
Pinhole ..	...	291	...

In the diagram below the lens densities are plotted as ordinates, and the logarithms of the minutes of lens exposures as abscissæ. The curve ADB drawn through the loci so determined is a straight line. A line CD is now drawn at right angles to the density axis from the point .97 corresponding to the density of the pinhole patch, and from the point D where this line cuts the curve AB a vertical DE is dropped, cutting the log. exposure axis at a point E corresponding to an exposure of 2.255 minutes.

Hence, it follows that an exposure of 2.255 minutes with the lens is equivalent to a pinhole exposure of 291 minutes, or one minute with the lens =  $\frac{291}{2.255} = 129$  minutes with the pinhole.

But pinhole exposure = pinhole factor  $\times$  R. A. Exposure.  
or 129 = pinhole factor  $\times$  81.  
 $\therefore$  pinhole factor = 1.6.

The question now arises, is the pinhole factor 1.6 thus determined valid for the same pinhole at all possible plate distances? Is it a constant for the pinhole? My experiments show that such is not the case. As the plate distance from the pinhole decreases—i.e., as the R.A. exposure number decreases—the pinhole factor also decreases. This is clearly indicated by the results of three series of experiments tabulated below:—

	Distance of pinhole from plate.	R.A. Exposure	Pinhole factor.
I	128 m.m.	60.6	1.42
II	159 2 m.m.	68.2	1.49
III	254 m.m.	81	1.6

This fact that the pinhole factor increases with the A.R. exposure number shows that the rule usually given for quadrupling the time of exposure when the distance between the pinhole and plate is doubled is quite inaccurate. It shows, in other words, that the inverse square law of the intensity of light cannot be applied in pinhole photography with a view to determining the amount of photographic action on the plate. If with the low-light intensities prevailing in pinhole photography the photographic action were proportional to the light intensity, then the pinhole factor determined for one plate distance would be good for all plate distances. It would appear, then, that we have in these results an object-lesson in what Abney has called "the failure of a photographic law." The statement that with respect to the amount of photographic action, diminution in intensity of light can be compensated for by a proportional increase in the time of exposure is valid only in the case of lights of considerable intensity. When the light intensity is very low (as in the case of pinhole photography), then the state-

ment breaks down; and the time of exposure must be increased in a greater ratio than that in which the intensity of a feeble light is diminished in order to secure constancy of photographic action at differing plate distances.

It should be noted that the "pinhole factors" quoted in the above table are, to a close approximation, a linear function of the R. A. exposure numbers. Plotting the results given in the table, an approximately straight line is found to express the dependence between the two sets of variables. Whether the simple relationship indicated is merely a fortuitous result of experimental errors, or whether it is the expression of law, I would not venture at present to decide. The *approximate* linear relationship is, however, suggestive, and it will shortly be made the subject of further investigation. Should the existence of such proportionality be definitely established, we should be in possession of a simple geometric method for determining the correct pinhole exposure for any camera extension.

Experiments will also be undertaken with pinholes of larger diameter than .014 in. From what has preceded one would be led to anticipate that under otherwise similar conditions the pinhole factor will decrease as the pinhole diameter increases.

What, then, is the *practical* outcome of the work summarised in this article?

1. That the correct pinhole exposure is, with the small pinholes used in practice, always greater than that calculated on a basis of relative aperture ratios.

2. That the inverse square law cannot be applied in calculating relative exposures at varying plate distances from one another.

3. That using a pinhole made by a number 12 needle, the pinhole exposure factor by which the A.R. exposure numbers must be multiplied, varies from 1.6 to 1.42 as the plate distance diminishes from 254 m.m. to 128 m.m.

It will be seen, then, that the results so far obtained leave us yet far from the realisation of the aim and object stated in the second paragraph of this article. They turn out to be specific, and not general, in their nature. Still, these results are of such a character as to foster the hope that future work along the lines laid down resulting in a more extensive series of data of the same nature may ultimately result in some kind of exposure metre of general applicability in pinhole practice.

DOUGLAS CARNEGIE.

## THE SALON OF THE PARIS PHOTO-CLUB.

THE Salon of the Paris Photo-Club is held this season at the Palais de Glace, Champs Elysées, the Palace of Fine Arts of the City of Paris having been closed to all unofficial exhibitions by a vote of the Municipal Council. The fine galleries occupied two years running by the French Photographic Salon will now be given up to solitude and a collection of the stretches of paintings ordered by the town for decoration of public buildings.

The lighting of the Palais de Glace is excellent, and equally distributed over the panels specially erected round the parqueted rink; also the wall surface being considerably greater than that of the Petit Palais, the frames are further apart, and the general aspect infinitely more pleasing.

The Salon was opened on Saturday, the 16th, by M. Dujardin-Banmetz, Ministre des Beaux Arts, and M. Brown, Director of the Fine Arts Department of the City of Paris. Fifteen hundred people visited the Salon between two and six, amongst which many artists and several well-known art critics, such as de Meurville, de la Sizeranne, Bapst, etc.

The English School is represented by sixty-two frames. The standard of this carefully chosen collection is as high as usual, which is saying much, and we are particularly grateful to Mr. Craigie, who brought it together, for having added such an attraction to our Salon. The peculiar scheme of tone adopted by the English pictorialists at the outset has been noticed—not always favourably—by the French public and art critics. It has been partly modified since, and to-day the works of the staunch, or occasional, supporters of the sombre style suffer still more from the neighbourhood of pictures of a more modern and vivid character. Mr. Craig Annan unites the two opposite styles, and shows two very different pictures indeed, the "Portrait of Mr. Cunninghame-Graham" and a magnificent piece of colour, "The Thames at Hampton Court," whilst Mr. Hollyer with the "Portraits of J. Evans and Mr. Jovey," keeps to his original methods. Six pictures by the Baron von Meyer, an able member of our Photo-Club, are far in advance of what he has hitherto exhibited. Amongst these the portrait of Mrs. Käsebieber and an open-air portrait have attracted universal attention. Mr. Crooke sends a fine portrait of Miss Leslie St. John, Mr. Horsley Hinton two large landscapes, in his well-known and suggestive style, "Rylstone" and "Airedale," Mr.

Holding a well-balanced group of figures, "Music." "La Seine," by Mr. Latham, is an impressive view of Notre Dame de Paris. Mr. Latham, I see, has not been able to scuttle the big lighter in the foreground. I know that lighter, and its obstinacy, well, and can sympathise with the author. A pretty symphony in grey, by Mr. W. Cadby, and an excellent portrait of a lady, just right in definition and values: from Mrs. Cadby, Kipling's cat—but one would have liked to see the sulky back of the unsympathetic brute silhouetted against some lonely perspective of tall, straight trees—this from a literary point of view. Mr. E. Calland's "Freeman's Wharf" is essentially French in treatment (Mr. Calland may or may not take this as a compliment!). It is a striking example of the effect that may be extracted from otherwise uninteresting materials by a clever opposition between blacks and whites, a careful rendering of values, and the choice of a pleasing and artistic medium. "Mater Amabilis," by Mrs. Barton, is a well-composed group, for Mrs. Barton knows how to place her figures, but we do not find in this picture, nevertheless full of sentiment, the admirable quality of flesh texture that strikes us in "St. Ursula," by the same author—a fascinating composition in the simple, naïf style of the primitives—all but the hose of the model, which has a suspicion of modern sauciness. But the hand is a picture by itself. Further on a delicate sketch by Dr. Evershed "La Grue et La Bruine"; the Bank of England tour de force by Mr. Craigie, a clever piece of work full of dignity and individual expression; a sunlight effect by Mr. Blake, well thought out and finely treated; and two excellent landscapes by Mr. Moss. Mr. Barnett's interesting work reminds us of that of Mr. Crooke—reduced. His photographs have a steel-engraving quality that is most pleasing. The hand in "Joan of Arc" is worth studying, but—here is a case for the Puyo-Pulligny anachromatic lens—Mr. Charles Collett's nose and his ear partake of strikingly different foci!

Further on: "Mount St. Michel," by Mr. Cochrane. May I timidly suggest an improvement to this powerful apotheosis of one of the marvels of Brittany? I know the Mount well, I have visited it seven or eight times in the last fifteen years, and have been able to witness the decline and fall of Madame Poulard's cooking—proportional to the ever-increasing invasion of the most hideous herd of French provincial tourists I have

met. Now I feel obliged (notwithstanding my admiration Mr. Cochrane's talent) to admit the truth of certain criticisms I have gathered from the remarks of our more enlightened patrons. It has been said that in Mr. Cochrane's picture of St. Michel "looks small." And I think the cause of the rding of the motive lies in the enormous size of the white column that forms a background to it. Would Mr. Cochrane a more horizon-like style of cloud as a setting to the far y pyramid of rock and hewn stone—just as an experiment? the same author "The Barrel," an excellent piece of work a oily transparent browns. Mr. Keighley's pictures are ays remarkable in composition and full of sentiment. "The pherdess" and "The Halt" are good examples of the artist's onal manner; but he is undoubtedly at a disadvantage h his neighbours at our Salon on the score of the medium he chosen, which does not seem to allow of accents or differ-treatment of different textures. Many of the English, and eral of the American exhibitors appear to take little or no rest in this matter. Perhaps on the other side the French- give it undue importance. Nevertheless, Mr. Keighley's k has been greatly admired. So has Mr. Mortimer's, ose poetic rendering of the more wrathful moods of the an is quite unequalled. His pictures have been particularly iced in several of the leading papers.

The English exhibits are hung together on the central panel the left side of the room, and on the two adjoining panels ween the Photo-Secession and the Belgian exhibition, in ellent light.

Amongst the thirty-five pictures sent by the Photo-Secession find six by Mr. Alvin Langdon Coburn of very high quality. e portrait of Bernard Partridge has attracted quite special ice from the French artists, with the splendid effect of sun-ht and reflected light in "Wier's Close," Edinburgh. There a gamut of light and shade in this simple picture that gives

a rare satisfaction to the eye. Six striking contributions in monochrome and colour by Mr. Steichen, several by Mr. Clarence White, amongst which the "Flute de Pan" has been specially noticed. Mr. Stieglitz shows a fine study of horses and "The Canter," a picture full of suggestive atmosphere; Mrs. Käsebier, six pictures which are excellent examples of the extraordinary versatility of the talented author; Mr. Frank Eugene, two prints from etched negatives, of a very peculiar quality. The whole collection is of a very high order, and maintains the well-deserved reputation of the American school.

The Belgian School, after a momentary eclipse, asserts itself anew. Messrs. Misonne, Leys, Wetremis, and several others show more than promising work. Spain, who seemed to be quite out of the race up to now, is represented by Messrs. Carlos Fingo-Pisacca and Mabrit, who are laying the founda-tion of an interesting school. From Italy we have some delicate work by M. Guido Rey, and some good things by Messrs. Ciutto, Licino, Farini and Alfredo Ornano. The Latins are awakening.

Amongst the French exhibits the most noticeable are those of Major Puyo, monochrome and in colours, of Mlle. Laguarde, Geay, Dubreuil, Grimpel le Bègue, Besson, Bacquet, Manry. Dillaye, Sollet, Mlle. Massion, M. Hachette. The two last exhibitors show excellent examples of the Rawlins process. Bromide is nearly extinct in the French section—platinum is rare, most of the pictures being printed on pure gum bichro-mate, or so-called ready-made gum bichromate papers such as Fresson, Artistique, Hocheimer, or Artigue papers. Three exhibitors have adopted the oil process and many more will take it up later on. On the whole the exhibition is good—not so select as the Photographic Salon, for its purpose is broader and tends towards encouraging rising talent, but un-doubtedly superior to last year's show.

ROBERT DEMACHY.

## PHOTOGRAPHIC ETHICS.

The greater portion of a Lecture by Pirie MacDonald before the Washington (U.S.A.) Convention.

Webster describes as being the science of human duty. Every other profession that we know of that has been established any length of time has found itself forced to a system of ethics—a system of understanding, man to man, each to the other realises at a certain course is the only course which is right, and that all other courses are wrong.

Due to the fact very probably that this profession of ours is so comparatively recent of birth, we have not been able to get together and arrange a code of ethics. We know individually what we believe to be right and wrong, but we are all built differently, and that one man considers right the other man considers not quite right, and the result is instead of a line being drawn absolutely straight, it wavers, and the result is that we do have, as I heard marked only a short time ago, a lot of petty jealousies. My friends, I believe that they are not jealousies, but largely a lack of understanding of one another.

We have in New York City an organisation that has been putting people together in groups, and those people who have been associated most closely together have an infinitely better understanding of one another than any scattered set of photographers of the same number in the world.

### The Duties We Owe.

In considering this question of ethics—and, truly, I do not propose bringing you with a long dissertation on the science of right and wrong, but it is absolutely necessary to explain the proposition in order that I may logically draw to an end. In the ethics of photography we must have three vital points which we must consider. The first is.

1. That duty we owe to the patron.

2. There is the duty which we owe to the profession; and,
3. There is the duty which we owe to ourselves.

The duty that we owe to the patron is beyond any kind of question the first duty. Because of this unformed condition that we are in we have been prone to look on the customer, the patron, as common prey; a person from whom we are to extract absolutely everything which is extractable, and give him just as little as possible. When it comes to a matter of the rights of the customer in the negatives which we have made we have been very prone, many of use, to forget, or to, at any rate, elide the importance of the value of the privacy of the customer. We must definitely get down to some line of procedure; we must get down to an understanding, each photographer with the other, as to exactly how far the line of privacy does go, as to exactly what the customer is entitled to and as to exactly what the photographer is entitled to, so that if a photographer transgresses that law which we have agreed is to be followed, he will be cut off from communion with us because he is not an honourable man according to the voice of photography as expressed in its ethics.

There are many duties that we have to our customers. The duty of giving our best, the duty of giving our absolute devotion, honour, and unswerving fidelity.

### Duties to the Profession.

The duties to the fraternity are an entirely different matter. It is a secondary interest as compared with the duty to the patron, but it nevertheless is an exceedingly important one, the duty that you and I owe to one another. When a client comes in and mentions the name of my friend, instinctively I say, even while I do not agree, perhaps,

with his artistic theories; even while I think, perhaps, that his work is not what he might make it—I say: “Yes, my friend; a bully good worker.” A man who doesn’t say that of his friend is no friend, and we should all occupy the position of friends, one to another. (Applause.) That is the reason for ethics. It breeds equality, that there be no one man bigger than another, and no one man smaller than another. The motto of the New York State Society is “Equality.” Equality is the foundation of ethics. You will find as you look the matter over that unless there is absolute equality it is impossible to agree on any common ground. Unless there is the feeling of equality it is impossible to do that duty which we owe one to the other.

I claim that it is the duty of every photographer to every other photographer to lead the next man to the point that he believes is the proper one to occupy; not necessarily the right one, but the one he believes is the right one to occupy. And so we might follow this subject through.

### Dignifying the Profession.

Every once in a while somebody says we must dignify the profession, and beyond any question it is true; we must dignify the profession. We must dignify the profession by acting absolutely honourable every time. We are undignified as a profession. Frequently we do find people who do unprofessional things, things we know are unprofessional, and the result is that a while ago I went to an affair dressed as other gentlemen were dressed, and I believed myself entitled to as much respect as any man in the room, and a man who is in the rubber business said to me:

“Going to make a flash-light of the bunch?” (Laughter.)

And I said to him: “Are you going to sell some of your damned old rubber hose?” It was the only opportunity for getting even. But you know truly that if we go to an affair of that kind as a professional man we should not go disguised as waiters; we should go as professional people, do our work and get out and not crowd in in a suit of evening clothes and try to do two things at once. And if we do go in as gentlemen we should protect ourselves as I then protected myself.

When it comes to real fraternity; when it comes to getting together, really closely getting together and getting down to the essence of the term fraternity, there is one thought I want to give you. I believe it to be an absolute truth. I want you to remember that “what you give will be returned to you in kind.” I want you to believe with me that just so sure as you lead a fellow craftsman off with a lie, just so sure will you be lied back to. There are people who have had trust misplaced in them, but I believe that the average will hold mighty good, that every time you do give out honestly and squarely a piece of encouragement, a piece of heart, a piece of knowledge, that the same thing in kind is returned to you.

The only possible basis on which a code of ethics can exist is that we must give and not always take; that we must hand out what we believe to be right; that after we have agreed to a thing we must live up to it, even though it cuts.

### The Section Idea.

Over in New York State a couple of years ago it was felt that an organisation of photographers should be perfected. On looking the ground over we decided that a meeting once a year was not adequate. We found that out by experience, and our friend Seavy will probably remember the instance, that when the National Convention was cut off two years the thing didn’t go. If it had been put off for four years you wouldn’t have gotten even the officials together. The result was that away back in Chicago in ninety something or other we decided it was necessary to hold the national convention every year in order that it might be kept warm. The truth is that to hold a meeting once a year only, you only keep in touch by your fingertips, you don’t really get hold of one another; you don’t get on to each other’s favourite yarns and don’t know how much to discount—(laughter)—so in New York State we arranged to divide the State up,

secondarily to the State Society, into what we called sections. We have, for instance, in New York City a section composed of about forty-five members. Then there are centres at other points; at Albany, another centre about Rochester, and another section has recently been formed on the Hudson River centering at Ploughkeepsie, half-way between New York and Albany. The effect of that while this is only our second year there were 350 people at the convention. It is true some came from outside of the State, but the main part of them were people from inside the State of New York. In New York City we have over forty who attend the meetings of the local society regularly every month.

When we first organised the New York City section I went up and down Fifth Avenue and called on some of the people three and four times, but they said “No, no; the thing won’t go; we would like to go to accommodate you, as far as that is concerned, but there is Mr. So-and-so down the street—” and I got every man to go there as my personal friend, to meet me, because I wanted him to; and we got through with the business of organisation in about three quarters of an hour, and then they “chewed the rag” for three hours, just tickled to death to meet one another. People who had lived on the same block for years went there and didn’t know each other’s faces, and each believed the other man was a crook. (Laughter.) That, unfortunately, is the condition in other places. If you see a man from some particular town he says, “I like Mr. So-and-so” in such another town, “but the man in my town, he is bad.”

In New York we have the bitterest kind of competition. We do not get much more money for our pictures than people in smaller towns, where expenses are much smaller, while our expenses are enormous, and it means that in order to preserve ourselves we have to go in and compete, and the bitterest competitors are the best of friends in New York—you see the word comes in all the time.

Some of you are going to point to the fact that at this past meeting in New York there was a bit of friction between our section and the executive. I believe that we were right, and I guess that the executive believed as honestly that they were right, but the very fact of there being a division of idea proves the necessity for the section; in one town from the interest in another; it proves that there is a separated interest; it proves that Pittsburg needs something that the District of Columbia does not need; it proves that you are able to get together on a common basis of real friendliness in Pittsburg, and that you in Washington, having common interests, are able to get together.

We never admit any of these Women’s Christian Temperance Association people as members because it interferes with the wishes of the majority. (Laughter.) I am very fond of many of them myself, but I am a great believer in the law of the majority. We always arrange so that we have a bit to eat and a drop to drink and a couple of cigars to a man at our meetings, and we don’t stand around and wait for people to propose things. Men vie with one another in proposing. One says: “Old chap, I haven’t had a drink with you for a long time,” and the result is they are glad to see each other and there is a genuine fraternal feeling. You may say this is a long way from ethics. I want to tell you the section is the birthplace of ethics. I want to tell you it is not among people whose interests are absolutely alike, but among people whose interests are different, that ethics can be bred at all. Ethics are made to pull people together to some common end; to pull people together so that they really understand and believe each other.

I hear around the hall some one say, “Well, photographers won’t live up to it.” I am a member of a conference. In that conference one of the biggest men in America, one whose tongue yields English that burns, I called down so that he apologised publicly for suggesting that our profession was not up to the average—morally. I want you to know that we are better than the average—morally; that we can and do live together in peace and in harmony, if we know one another well enough. I would like to see you folks next year form a dozen groups and try the scheme out.

COLOUR photography, according to a halfpenny daily paper, is too correct for portraiture, inasmuch as it may render the eye of orange colour should the sitter accidentally wink at the moment of exposure. This remarkable phenomenon is noticeable in what our contemporary calls the “Sangard-Sheppard” process.

A PRESENTATION took place last week to Mr. W. F. Judge, manager of the Lancashire and Yorkshire Portrait Co., Ltd., at their Dublin branch, 58, Capel Street. The presentation, which took the form of a purse of sovereigns and a gold watch, was subscribed by the staff and outside friends.

# THE BASIS OF THREE-COLOUR PHOTOGRAPHY.

(Translated from "Das Atelier.")

All methods of three-colour photography the coloured image is obtained by the combination of three monochromes, which either of a material nature or are formed by reflection or proportion of coloured light. To the former class belong the transparent pictures on films or glass, three-colour carbon prints, or are produced by imbibition processes like pinatype. It is immaterial how they are made, whether superimposed or printed one on top of the other.

The pictures are, however, formed in quite a different way in three-colour reflection or projection methods. In the latter they are projected by a triple lantern on to a screen; in the former apparatus such as a chromoscope is used.

## Subtractive and Additive Synthesis.

In the three material pictures are placed one on top of the other, the colours are formed in exactly the same way as though the dyes themselves were mixed, whilst by superposition of the images on a screen the phenomena observed are those produced by the mixture of coloured lights. When mixing powdered or dissolved colouring matters a dark compound colour is always formed; if to the mixture a third dye is added the colour will become darker, and, with suitable choice of the components, black can be formed. With every new addition of dye some of the reflected rays of light are absorbed, and such material mixtures are therefore called "subtractive synthesis." If, on the other hand, coloured light is projected on to a screen and then on to the same place light of another colour is thrown, a compound colour of greater brilliancy is formed, every part of the surface is illuminated by two sources of light. Thus with every further colour the brightness of the mixture increases, and with suitably chosen colours white is formed. The mixed lights are added, therefore in this case we talk of "additive synthesis."

## What Should the Filters Be?

The constituent pictures in both cases are obtained, as is well known, by three photographic exposures on the original behind coloured filters. This process is called photographic colour decomposition, separation, or analysis.

It is obvious that in this analysis of colour the later coloration of the three constituent images must be borne in mind, for the components produced by photographic means should combine to give a result similar to the original. Another question is whether the separating up of the colours should be effected in the same way, whether the two methods are only to be differentiated by the mode of synthesis, or whether in the colour analysis other principles must come into play, because perhaps the theoretical principles of the two processes are different.

To present the general opinion is to accept the latter view, for the line is rigidly drawn between additive and subtractive filters in the exposures. Further, for three-colour projection for obtaining constituent coloured images, those colours must be chosen which correspond to the three fundamental sensations of the Young-Helmholtz theory of colour vision, whilst quite independent of these in similar processes of three-colour printing, the constituent images are stained blue, red, and yellow.

The above considerations necessitate a clearing up of the facts, and bring into prominence the following questions which require answering:—

What is the difference between the additive and subtractive colour mixtures.

How important is the Young-Helmholtz theory in three-colour photography?

What colours should be chosen as the fundamental colours?

What difference exists between the additive and subtractive colour mixtures?

How should the filters be adjusted to a given make of plate?

## The Difference Between Additive and Subtractive Colour Mixture.

The following are the fundamental laws for the mixture of coloured lights:—

If two coloured lights are mixed there is always formed together

with the compound colour, which lies midway between them, a certain amount of white.

2. If one of the mixed lights alters continuously the appearance of the mixture also alters continuously.

3. Lights of similar appearance always give similar mixtures. The quantity of white which is formed in the mixture is greater, the greater the difference or separation of the colours of the components, and the mixture of complementary colours is white. The brilliancy of the mixed colours is increased by the proportion of white, but the saturation is decreased.

The second law requires a systematic continuity of the compound colours, it insures the rigorous connection between the gradations of the constituent prints and the compound colours formed by their combination.

The third law requires special examination, for from this it is obvious that light compounded of complementary colours behaves exactly like simple spectral colours. The spectrum peculiarities of the lights used in three-colour projection—that is, the absorption ratios of the so-called reproduction filters—are without any influence on the results, and one has only to take into consideration the colour and saturation. The three coloured lights, therefore, when suitably chosen, give as pure a white as when simple spectrum colours are used.

In the additive methods of three-colour photography, as is well known, three positives are made from the negatives. They are covered with vermilion-red, ultramarine-blue, and yellow-green glasses, and then projected one on the other on a white screen or combined by means of mirrors in a chromoscope.

All other colours are formed by the mixture of these three components, and these colours are generally called the fundamental colours for the additive three-colour synthesis. That is, however, only partly correct, for one may equally as well consider those colours fundamental which are peculiar to the three positive constituent images which form the complete picture. The constituent images do not show the above-mentioned colours, but blue-green, yellow, and purple-red.

In triple projection one of the lights is cut out by each positive, and therefore the latter appears on a white screen in the compound colour of the two other lights. If, for instance, a positive is placed in front of the red light, a blue-green positive image is formed on a white ground, and in the same way the blue and green projection images will give yellow and crimson images. The three constituent pictures thus show the same colours as those which are used in the so-called subtractive methods of three-colour photography, and their combination corresponds equally then to a subtractive method, for by their mixture there is formed not white but black. The second and third laws are, however, absolutely maintained.

By this statement a very clear connection between the two methods of three-colour photography is obtained; whilst, with the additive mixing of coloured lights, the spectrum composition plays almost no part, in the mixing of material colours, whether by the combination of powders or solutions or by the superposition of stained transparent films, the results depend essentially on the spectrum composition of the components.

With regard to this, the following rule may be laid down: If the absorption bands of the colours to be mixed overlap, the rules stated above for additive light mixture approximately applies to the subtractive colour mixtures, with this difference, that black and not white is formed with the compound colour. Suitably chosen colours thus behave exactly like spectrum lights if the tone of the compound colour only is considered.

As a proof of the difference between an additive and a subtractive colour mixture it is usually advanced that yellow and blue lights when mixed give white, whilst yellow and blue colours combine to a green. This difference only exists, however, according to the various ideas of "blue" and "yellow," for yellow and blue dyes also give colourless mixtures, when they are so chosen that their colours correspond to complementary lights. If this is denied, one must also declare the formation of a neutral grey impossible. This grey is only formed from a blue, which is formed of crimson and blue-green, and the third fundamental colour, yellow.

If the absorption bands overlap, then variations always appear, which can scarcely be determined beforehand except by intimate study of the spectral composition of the colours.

If thus, for the two processes of colour photography, constituent images are used of equal colour, and if in the subtractive method colours are chosen which answer to the above requirements, there is—at least, theoretically—no impediment to prevent one from obtaining very nearly equal results. In practice, in the preparation of material three-colour prints, however, far greater difficulties have to be overcome, for the blackness of the pigments, their insufficient transparency, as well as the want of stable dyes which answer to the theoretical spectrum composition depreciate to a great degree the final result.

The blackness of the pigments is especially troublesome; it is particularly noticeable when the colours are impressed on paper, because then only the weak light reflected from the white paper has to be considered, and this the coloured films only allow to pass in a very incomplete way. Transparencies illuminated by a brilliant light appear much purer, even if they hardly attain the purity of the optically projected images. If the impure constituent images are combined, the blackness increases unduly, for it is in logarithmic projection.

If we mix white with black, there is obtained even with 50 per cent. of black a very bright grey, in which no one would suspect the high proportion of black. If, however, the addition of black is gradually increased, this at once becomes unduly noticeable. From Fig. 1 will be seen the connection between the quantity of

Fig. 1.

black actually present and the subjective sensation. A green, for instance, which contains 50 per cent. of black, appears to us relatively pure, for we have the sensation that it is only degraded by 10 per cent. of black; if, however, we add to this green just so much of the complementary red that the proportion of black is further increased 25 per cent., the colour has a very impure impression, for we recognise in examination almost as much black as green. An objective proportion of black amounting to 75 per cent. corresponds practically, as the diagram shows, to a subjective sensation of almost 40 per cent. of black.

By this fact the difference between the various three-colour images is clearly defined; the three-colour projection images or the chromoscope pictures are extremely pure, therefore an increase of black by admixture of the complementary colours will only be slightly recognised, whilst the impure pigmentary images when combined must by the simultaneous increase in black have an unpleasant dirty appearance.

### Does Young's Theory Apply in Three-colour Photography?

A hundred years ago Thomas Young tried to explain the perception of all colours by only three independent colour-sensations. He assumed that in the eye there were three nerve fibrils, the excitation of which caused the colour sensations. The excitation of one nerve gave rise to the sensation of red, that of the second produced green, and that of the third violet. If all the nerve fibrils

were equally excited we recognise the sensation of white, and with simultaneous excitation, but in different degrees of two or three of these nerves, all possible colour sensations are explained.

In order to support this theory, which was later more fully worked out by Helmholtz, the proof must be brought forward that the three elementary colour sensations actually suffice to explain the whole scheme of colours—that is to say, that by the simultaneous action of red, green, and violet light on our eyes any possible colour sensation can be produced.

As every colour can be split up into the simple colours of the spectrum, the proof of Young's theory will be obtained if the formation of all spectrum colours is effected by mixture of the three components which correspond to the three fundamental sensations and which can be called the fundamental or primary colours.

Thus we have here a physiological problem to solve, in which we must note not only the formation of the spectral colours as regards hue, but also as regards their saturation. If, for instance, two complementary spectrum colours—for instance, violet and yellow-green—are mixed so that white is formed, there is, according to the discrimination of our eyes, a much smaller quantity of violet than yellow-green required. The spectrum colours thus possess a different degree of saturation; violet is the most saturated then follow blue, red, orange, green, and yellow.

Young chose the most widely separated colours in the spectrum—the red, green, and violet. When, however, later experiments in mixing these were made, it was not found possible to produce the intermediate colours with their full saturation. If, for instance, the extreme spectrum red was mixed with the green of the E line, a yellow was obtained which agreed in hue with the spectrum yellow, but which was too white. If a yellower green was used so that a better yellow was obtained, then the mixture with violet gave a too whitish blue. With the three spectrum colours chosen the intermediate colours could be indeed obtained, but not of sufficient saturation.

One is forced to the conclusion, therefore, that the fundamental sensations must correspond to much more saturated colours than those of the spectrum. These supersaturated primary colours cannot be produced, as the spectral colours are the most saturated that we know; they can only be numerically estimated, and calculation proves that Young's theory is actually in accord with these hypothetical fundamental colours.

Besides the previously mentioned experiments of mixing the spectrum colours, others were made to clear up the question of the primary colours. The experiments with colour-blind persons were of great value, as were also the phenomena of visual fatigue as shown by our eyes after the continued action of different colours.

The fundamental colours determined by various experimentalists agree so far, if the saturation is excluded, that they may be generally called red, green, and violet or blue, yet they show considerable differences.

König and Dieterici, F. Exner and V. Grünberg, have fixed on a bluish-green for the fundamental green; Clerk Maxwell and Helmholtz choose a yellowish-green. The statements as to the primary blue vary between a greenish-blue (V. Grünberg) and a blue-violet (Maxwell), whilst there is a fairly unanimous consensus as to the extreme end of the spectrum being called the primary red.

With these primary colours the physiological process of colour vision has been explained, and it will now be seen that there is no authorisation to consider the same as the fundamental colours for three-colour photography. If we had only to reproduce the spectrum colours with their peculiar saturation, and to deal with colours of similar quality, the physiological primary system would be the correct one. Three-colour photography has, however, quite another problem to solve, for by its aid we have to reproduce the world of colour that lies around us, and to reproduce it equally correctly.

The difference between the two problems is best explained graphically.

Let us imagine a circle (Fig. 2) on the periphery of which are all the colours in continuity from red, through yellow, green, blue, and violet; further, that each colour extends over an equal space; further, that in the centre of the circle O there is white, and that in every radius between white and the peripheral colour lie whitish shades of that colour. Every two colours which are at the opposite ends of a diameter are complementary, and their intensity such that

mixing them they give white. The surface of the circle is then mixture surface, every diameter a mixture line, and the result of mixtures of colours can be geometrically determined by the circle of the centre of gravity.

Fig. 2.

in this surface we trace every point which corresponds in hue relative saturation to the spectrum colours, the result will be curve of approximately the form of the thick line curve in Fig. 2. Colours are thereon designated by the letters of the Fraunhofer spectrum. The spectral blue violet and the red are the most saturated, and are therefore the furthest from white, or O, the centre, whilst blue, green, and blue-green, being considerably less saturated, lie

further from the circumference. The spectrum, blue-violet of the G line, should be assumed to lie on the periphery, and therefore all peripheral colours must be as saturated as this. If the colours of this curve are to be imitated by means of the three fundamental colours, they must be so chosen that the mixture triangle must enclose the spectrum curve. The simplest plan is to choose those colours lying in  $a$ ,  $b$ , and  $c$ ; equally saturated colours—for instance, those lying in  $a^1$ ,  $b^1$ ,  $c^1$ —may be chosen. If one assumes still more brilliant colours as the primaries, then the mixture triangle may have any possible position as long as it encloses the spectrum colours.

Other requirements are apportioned to those fundamental colours which should be used for three-colour work. They are not required to possess the saturation of the spectrum colours, for the colours of objects which surround us do not reflect homogeneous spectrum light, but mixtures of the same, and these have always a less saturated appearance. But it must be possible to reproduce all colours of equal saturation, for in the world of colour round us we find yellow and green as saturated as blue and red, and, further, violet and purple, which do not exist in the spectrum, must also be considered. Material colours are also spectrum colours, and the ratio of the mixtures must thus be so arranged that colours of equal saturation are formed.

If we assume that the material colours to be reproduced lie on the periphery of the circle K, they cannot be reproduced by mixture of the physiological colours  $a$ ,  $b$ ,  $c$ , or  $a^1$ ,  $b^1$ ,  $c^1$ ; the three colours symmetrically disposed in the colour circle  $a^{11}$ ,  $b^{11}$ ,  $c^{11}$  are selected to satisfy these requirements. Therefore the choice of the three colours is quite immaterial, for the triangle  $a^{11}$ ,  $b^{11}$ ,  $c^{11}$  may be rotated at will, and yet always enclose the circle K. If the physiological colours are to be used, then only those colours of equal saturation but of whitish hue lying in the circle  $K^1$  can be obtained.

Coloured lights or dyes, which correspond to the physiological primaries, do not, therefore, equally apply to those material colours which we have to reproduce by colour photography. If such primary colours are used in optical synthesis, only very whitish compound colours will be partly formed, and in subtractive synthesis very black compound colours.

From these considerations it ought to be clear that the Young-Helmholtz theory of colour vision possesses no importance, for the theory of three-colour photography, and that it is therefore not correct to identify the physiological fundamental colours with those of three-colour photography.

A. VON HUEL.

## A COOL STUDIO.

A GLASS house is a veritable trap to catch heat, a fact of great advantage to the gardener, but at times awkward for the photographer. A restful coolness and (what is almost as necessary) an absence of coolness is vital during summer. First and foremost, good ventilation is needed. The theory of an unventilated place is stagnant and depressing. Take a person into such a room and she wilts and tires. Where available, the number of windows should be open—the more windows the less chance of draughts. Whenever sitters are not actually in the studio it is feasible, and often several windows may be open even when work is in progress. But a good blow through is only a part of ventilation. The quiet, automatic sifting of air through ventilators is needful at all times, for there are seasons in spring and fall—in winter, too—when windows cannot be opened, but when changed air becomes as foul and stagnant as in the heat of summer.

### Ventilation

Ventilation must be carried out with some attention to the methods of air. It is well known that if air is passing out from the top of a room it causes a draught under a door. The outgoing air, in short, must be replaced. If the door be sealed so that cannot pass under it, the room will grow stagnant in spite of a hole at the top. Air exhibits a disinclination to pass out and by the same aperture. If a lath, or even a cord, be stretched across the hole to divide it in two it will be found that a current of air starts. So with our ventilators, we need more than one;

and several small ones work better than two larger ones. A row placed high in the slant and another row close to the floor will act best. It is commonly supposed that air comes in through the lower and passes through the upper ventilators. This is not necessarily so. Air does not float upwards in itself naturally; only when it is heated. In a room of stagnant air the flow may be downwards. It is possible to have a pool of "bad" air either at the roof or the floor; and so it is advisable to have ventilators near each. A single window opened does little good. If opened top and bottom a flow of air commences.

### How to Suggest Coolness.

Fresh air attained, it is next necessary to have suggestions of coolness. A red-plush upholstered chair is an abomination on a blazing day. If such a chair is in use it might be temporarily covered with some calico wrapper in a good photographic cool colour, or a chintz of quiet, unobtrusive pattern. A wicker chair is better, and sometimes a deck chair, or even a hammock, is better still, though both may be used for unsuitable people unless the photographer is careful. Artificial plants should be retired and cool-looking growing ones used instead. Some of the lilies which grow in china bowls containing only pebbles and water are excellent for this purpose. Light thin draperies sometimes help the effect.

The skylight frame is, of course, painted some light, cool shade. In some studios a little extra painting in cream or green or some such tint will help the general effect, as will a certain amount of shade. If the sitter passes from a dark dressing-room into a bright

studio, heat is at once suggested. If the dressing-room is brightly lit and the studio screened, the suggestion will be coolness.

Water has a restful look, and it should be used. But water must be clean and clear, and a globe of goldfish is a pretty ornament, and as good as a toy when children are present.

#### Hot Weather Memoranda.

Children, by the way, are thirsty little mortals, and often a fractious child is merely a thirsty one. A filter—one of those glass ones in which the drip, drip of the water may be watched—should be in every studio. A block or chips of ice floating in the water will ensure coolness.

In hot weather we are not content with fresh air; we must feel the flow of it. A few hand fans should be in every studio, either Japanese paper fans or palm leaves. The latter usually look better. And electric fans that do not buzz too much will send cool currents across the studio.

Last, there is the operator himself. I have visions of a terrible sight, seen a quarter of a century ago. It was an old line "professor," with somewhat long hair streaming over the collar of a velveteen jacket. The day was a hot one, the studio stuffy, and the professor was mopping himself with a large brown-and-gold silk handkerchief. Poor little sinner! no wonder the child was fractious. There is no need for an operator to wear black, if it is not in keeping with the day. He should look cool and comfortable, even if he has to don white to do so. It is not what is but what seems.

#### ON THE INSOLUBILISATION OF GELATINE BY THE OXIDATION PRODUCTS OF PHENOLIC BODIES.

We have already shown that the insolubility of gelatine produced by a pyrogallol developer is not due to the pyro but to the oxidised product. (B.J.P., April 13, 1906.)

We have also shown that the possibility of obtaining, under certain conditions, that it is possible to produce the same result under certain conditions with other developers of the phenolic group.

The present researches were undertaken to see whether the same effect was peculiar to the phenolic compounds which are developers, or whether it was common to all phenols. Gelatine was treated with the solutions in three different ways (a) with an aqueous 1 per cent. solution (b) with a 1 per cent. aqueous solution with 3 per cent. of anhydrous sodium carbonate added, and (c) with a 1 per cent. solution with 3 per cent. of anhydrous carbonate, and 3 per cent. of anhydrous sulphite of soda.

Comparative tests were made in bottles full and half full, and open and closed with the following substances: Ordinary phenol, paracresol, naphthol,  $\beta$  naphthol, resorcine, gallic acid, tannin, dioxy-naphthaline, phloroglucine, salicylic acid, paranitrophenol, and naphthol monosulphonate of soda (1.4), and  $\beta$ -naphthololsulphonate of soda (R. salt 2.3.6).

In closed bottles none of these solutions render the gelatine insoluble in boiling water. When exposed to air insolubilisation is produced by some of these solutions, but only under the conditions observed with the developer—that is, in the presence of carbonate of soda.

The following table gives the results of the tests:—

1 per cent. Solution with 3 per cent. Anhydrous Carbonate of Soda exposed to the Air.	Time approximately necessary to produce Insolubility in Boiling Water. Days.
Gallic acid .....	2
Tannin .....	4
$\alpha$ naphthol .....	25*
$\beta$ naphthol .....	5
Resorcine .....	45
Phloroglucine .....	5
Dioxy-naphthaline .....	5

The alkaline solutions most readily oxidisable, such as gallic and tannin, produce insolubilisation after a long time in the presence of sulphite, probably because they oxidise more slowly. All the solutions which act are coloured more or less dark brown, and the gelatine is also stained.

\* In the oxidation of  $\alpha$  naphthol a brown precipitate is formed which was not observed with  $\beta$  naphthol, which probably explains the more rapid insolubilisation with the latter.

These results prove that phenols, which are not developers, possess the property of rendering gelatine insoluble, whilst the developing function plays an important part in the rapidity of action. Resorcine only acts after a month and a half, whilst under the same conditions hydroquinone acts in one day, and pyrocatechin in two days. The results obtained with resorcine prove that quinone compounds are not the only products of oxidation which produce insolubility. The formation of quinone cannot be assumed to take place in the case of resorcine.

A. AND L. LUMIERE AND SEYEWETZ.

#### ASSISTANTS' CERTIFICATES.

THE following are the conditions under which the new "registrars' certificate" of the Professional Photographers' Association is granted. They are quoted from the No. 6 "P.P.A. Handbook," just issued:—

In accordance with the notification of the committee at the time the original prospectus was published, that the matter would be fully reconsidered in the light of a year's experience, a sub-committee appointed by the committee invited criticism of the existing scheme from those assistants who applied for prospectuses and went further. The replies were fully considered, and the whole bearings of the scheme carefully discussed. The information derived from assistants themselves was a valuable help towards the realisation of the defects of the scheme from the employes' point of view, and, beyond that, the correspondence disclosed that the prospectus itself was too elaborate and detailed to be easily understood by the majority of the class to whom it was addressed. In several cases it was perfectly clear that it was entirely misunderstood. It was made abundantly evident that a large proportion of the photographic assistant throughout the country are not capable of classification according to any specialised character of their work, but are employed generally as all round hands, and also that their earnings are not, as a rule, much more than sufficient to meet the cost of living. It has been decided, therefore, to satisfy the requirements of this class by instituting a new grade of certificate, to be entitled "The General Assistants' Certificate," and, in order that there may be no excuse for not applying for the certificate on the ground of its being too expensive, it has been resolved that applicants be charged only the registration fee of One Shilling.

The work of the general assistant being necessarily varied in character, the method of determining the candidates' qualification adopted with regard to classified assistants cannot very well be applied, and a new method is adopted. The candidate is required to state his qualifications, and the certificate is given for those which are upheld by present and previous employers.

The following are the directions issued to applicants:—

#### GENERAL ASSISTANTS' REGISTRATION CERTIFICATE.

Applicants for these certificates are required to furnish a list of the various branches of photography in which they claim to be proficient, and also to state the names and addresses of their present and previous employers, with period of service with each, giving dates of entering and leaving if possible.

If the qualifications claimed are confirmed on inquiry of the employers, and the examiners are convinced of the ability of the applicant, the association will grant a certificate setting forth the grounds upon which it is granted, and the particulars of the holder's employments.

Each application must be accompanied by a postal order for one shilling, as a registration fee. No further fee will be charged. As direct inquiry is made of present and past employers, testimonials and references should not be sent.

A Register of Certified Assistants will be kept by the association, for the use of employers requiring assistants.

Holders of certificates, when advertising for situations, are recommended to add the words "P.P.A. Certificate" to their advertisements.

Certificate holders are entitled to receive the advice of the committee of the association upon any matter connected with their photographic employment.

# PRESIDENT'S "AT HOME" AT THE PHOTOGRAPHIC CONVENTION.

announce on another page, the Wednesday afternoon of Con-  
n week will be left open for members to accept Mr. Hum-  
s invitation to join him in a marine excursion down South-  
n Water, an item in the programme which should be accept-  
ven to those who entertain fears of mal de mer whenever they  
board ship, for Southampton Water is almost always as calm  
pond, the vessel, "The Duchess of Kent," is the best boat  
Solent waters, and she will make her journey at half-steam  
e those on board an opportunity of photographing the yachts  
their craft in the water. In addition to these attractions, the  
ese Band of Herr Carl Heubert will accompany the party,  
will perform the following programme of music:—

arch .....	"Welcome" .....	Kral.
altz .....	"Aquarells" .....	Strauss.
lection .....	"Romeo and Juliet" .....	Gounod.
ng .....	"Erublingsluft" .....	Reiterer.
altz .....	"Lysistrata" .....	Linke.
lection from "Lohengrin" and "Tannhauser" .....	Wagner.	
renata .....	Tschaikowsky.	
alse .....	"Bei uns z'Haus" .....	Strauss.
lection .....	"Veronique" .....	Message.
skewalk .....	"La Kraquette" .....	Clerice.
lection .....	"Faust" .....	Gounod.
arch .....	"King Cotton" .....	Sousa.

every respect, therefore, the Presidential "At Home" can  
r help being one of the most enjoyable of occasions, and  
hich, in years to come, will mark out the Southampton Con-  
n as offering a commendable variation from the stereotyped  
a party which has come to be regarded as the inevitable  
y of the Convention on the Wednesday afternoon of its week.

## THE PROPOSED CAMERA CLUB.

OWING on the meeting recently held at the Charing Cross Hotel  
rting the scheme of a camera club in the West End of London,  
are being taken to secure the necessary interest and support.  
a circular which has been issued it is explained that a club is  
cess of formation, the object of which is to provide a meeting  
for those interested in the practice of photography as a hobby;  
ain idea being that such facilities shall be afforded so that e  
becoming a member will find he has the use of completely  
ped club rooms, enlarging, day and electric-light printing and  
rooms, and several dark rooms, together with the opportunity  
aining instruction in photographic matters.

s stated that the following membership is required:—  
50 to 300 town members at an annual subscription of £2 2s.  
3 country members at an annual subscriptions of £1 1s.  
rance fee £1, for which a £1 share in the syndicate or company  
be issued, but after the first 325 members have joined there  
be a further entrance fee.

re would be no liability to members beyond the payment of their  
ace fee and subscriptions; under these conditions the club  
be a Members' Club, with limited liability.  
start the club on a satisfactory basis financially a small syndicate  
npany will be formed with a capital of £600 in £1 shares, bear-  
per cent. interest, and a reserve fund will be formed out of any  
s profits and future entrance fees.

urly one hundred gentlemen have already expressed their desire  
ome members, and about £120, exclusive of entrance fees, has  
promised towards the capital required. The club room will be  
led with daily and weekly papers, and the photographic period-  
nd writing materials. It is proposed to supply light refresh-  
s, and to hold during the winter months demonstrations on  
graphic subjects for beginners, as well as for more advanced  
rs.

lies will be admitted to the studio, but not to membership of  
lub.

e committee invite all those qualified for membership, and desire  
se use of the club and its facilities, to support them in this move-  
and at the earliest opportunity, to send in their names, or if  
urther information is desired, the Honorary Secretary, H. W.  
olme, Blenheim Mansions, Queen Anne's Gate, S.W., will be  
y to afford it.

## BOGUS PHOTOGRAPHERS.

WE are glad to see the "Daily Mail" exposing the tricks of the  
impostors who pose as photographers, which it does in an article as  
follows:—

We have met him in various guises—the man who, under some  
pretext, obtains admission to a house and then quietly appropriates  
any articles of value he can see.

His last impersonation is as ingenious as it has proved successful.  
He poses as a photographer, and, duly armed with his tripod and  
accessories, he calls at the house of a lady who lets apartments.  
He asks no fee, but explains that he is calling on behalf of a high-  
class magazine devoted to the apartment-letting industry. He  
wishes merely to take one or two views of the interior for the  
purposes of reproduction in this nebulous publication, a copy of  
which will be forwarded.

The gratified landlady allows him to fix up his apparatus, when  
he discovers something has gone wrong. Can the lady find a screw-  
driver and a hammer? The lady goes off to find the articles he  
requires, and in her absence the "photographer" conceals about  
him any valuable trifles that may be lying about.

On his victim's return he announces that he has rectified matters  
and taken the photograph. He engages her attention while packing  
up his things by chatting genially, and the loss of the valuables is  
discovered too late.

The police state that this branch of fraud and theft is quite new  
to them, and that it is doomed to as short a run as the "electric wire  
inspector" (who asked his victims to go to the top of the house and  
ring electric bells), the bogus water-tap inspector, and the man with  
the new gas-bracket (ordered by the master of the house and subse-  
quently found to have been a mistake). All call with guileless  
objects and leave the richer by any silver ornaments that may be  
lying about.

The camera figures in another and even more irritating form of  
fraud, where a man pretends to snap-shot a private house for repro-  
duction on a dozen picture postcards receives a deposit, and decamps.

## Photo-Mechanical Notes.

### The Cost of Making Half-tone Engravings.

It is to be feared that few photo-engravers are able to say what it  
costs them to produce half-tone and line blocks, and many quotations  
perhaps are based not as they should be on cost of production, but  
on the alleged price at which a competitor offers to do the job.  
Attempts to fix a regular price per inch are never likely to succeed,  
and we fear efforts made with the aim of fixing a minimum price  
per inch are similarly unlikely to be of any service, for the reason of  
the very great danger that such fixed minimum will become a maxi-  
mum. But these movements towards standard prices will prove a  
boon to the photo-engraver if they do no more than compel him to  
enquire into the actual cost to him of the work he turns out. On this  
subject we quote a letter from Mr. Geo. H. Benedict, of Chicago, one  
of the largest photo-engravers in America, from the current issue of  
Penrose's "Process Work."

"For several months" (writes Mr. Benedict) "we have kept an  
accurate record of the number, size, and shop cost of all the half-  
tones and zinc etchings we have turned out.

In the shop cost we include wages, material, rent, power, and  
light, but not the cost of any work charged as extras, or any portion  
of the office expense.

The result is:—The shop cost of all half-tones was 9c. (4½d.) per  
square inch, the average cost per cut was \$1.48 (6s. 2d.), but it is  
certain that cuts under the average size cost more per square inch  
and less per cut, and cuts over the average size cost less per square  
inch and more per cut.

Our theory is that the approximate cost of a half-tone of any size  
is one-half the average cost per cut, plus one-half the cost per square  
inch, and by combining the square inch cost, and the average cut  
cost, we have the true proportion of a fixed charge and square inch  
rate, and a consistent selling price that will afford 100 per cent. profit  
on the shop cost, and allowing 25 per cent. for operating expense,  
advertising, etc., a net profit of 25 per cent.

Using even figures, and assuming that a fair day's work for each photographer and the crew to complete the cuts is as follows, the result of basing the selling price on a fixed charge of \$1.50 (6s. 3d.) per cut plus 10c. (5d.) per square inch is:—

20 10-inch cuts at \$2.50 (10s. 5d.) each is \$50.00 (£10 8s. 4d.) for a day's work (or 200 square inch at 25s. (1s. 0½d.) per square inch).

16 25-inch cuts at \$4.00 (16s. 8d.) each is \$64.00 (£13 6s. 8d.) for a day's work (or 400 square inch at 16c. (8d.) per square inch).

12 50-inch cuts at \$6.58 (27s. 5d.) each is \$78.00 (£16 5s. 0d.) for a day's work (or 600 square inch at 15c. (7½d.) per square inch).

10 80-inch cuts at \$9.50 (£1 19s. 7d.) each is \$95.00 (£20 4s. 2d.) for a day's work (or 800 square inch at 11 7-10c. (about 5½d.) per square inch).

From this it will be seen that \$2.50 (10s. 5d.) each for 10-inch cuts would be less profitable than 80-inch cuts at 11 7-10c. (about 5½d.) per square inch.

As to zinc etchings—the result of our investigation is that the cost per square inch and per cut is approximately one-half the cost of half-tones. It is, therefore, reasonable that to afford an equal profit, zinc etchings should be sold at one-half the price for half-tones."

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications have been made for Patents from June 5 to 9:—

MASK.—No. 12,994. Improved form of mask for printing from photographic negatives on photographic papers and postcards. Arnold Moritz, 39, Fitzjames Avenue, West Kensington, London, W.

DAYLIGHT LOADING DEVICES.—No. 13,038. Improvements in devices for loading photographic cameras with plates, films, etc., in daylight. P. M. Justice for Emile Wunsche, Aktien Gesellschaft für Photographische Industrie, Germany.

FOCAL-PLANE SHUTTERS.—No. 13,107. Improved photographic focal-plane shutter. Louis Borsum, 18, Southampton Buildings, London.

CHANGING BOXES.—No. 13,351. Improvements in photographic changing boxes. Optische Anstalt C. P. Goerz Aktien Gesellschaft, 31, Bedford Street, Strand, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

ROLL-FILM.—No. 16,999, 1905. The claim in regard to this invention is for "a photographic film constituted by two gelatine silver emulsions or sets of emulsions and an intermediate transparent flexible base of non-absorbent material, such as celluloid, the emulsion or set of emulsions on the one side of the base being relatively faster than the emulsion or set of emulsions on the other side." Leonard Smith, 22, Park Hill Road, Croydon, Surrey.

PRINTING FRAMES.—No. 13,817, 1905. The novel form of frame consists of one in which sliding spring clips are provided on the clamping back of the frame, which back is hinged in several places, and may be attached at one end to the other portion of the frame. John Lewis, Villette, Kenilworth Road, Berkswell, near Birmingham.

COLOUR-PHOTOGRAPHY.—No. 6,881, 1906. The claims are for different patterns of colour screens built up of triangles, hexagons, or rhombuses, so as to fit together without intervening spaces or overlapping, a quantity or the whole of these geometrical unit areas being coloured, and so arranged that at every point where the unit areas, whether of triangular or compound nature meet, all the colours occurring in the screen are represented once or more fold. In the accompanying drawings some examples of such a colour screen are depicted. In the screen shown in Fig. 1 equal sized equilateral triangular unit areas (a) fitted together without intervening spaces or overlapping, are grouped together to form regular hexagons. In the colour screen, Fig. 5, in which

the areal division is the same as Fig. 1, the three colours which have to be considered in three-colour photography (R = red, B = blue-violet, G = green) are grouped once round every point where three hexagonal elements meet. Fig. 2 represents a screen divided into equal sized equilateral triangular unit areas fitted together without intervening spaces or overlapping. In the colour screen shown in Fig. 6, in which the areal division is the same as in Fig. 2, six differently coloured elements are grouped once round every individual central point where six triangular elements meet. These six colours (R = red, B = blue, G = green, O = orange, Y = yellow, V = violet) would be suitable for a method of six-colour photography. In the case of the colour screen shown in Fig. 8, in which the areal division is the same as in Fig. 2, the two colours suitable for a system of two-colour photography are grouped alternately three-fold round every point where six triangles meet; the black areas representing the orange coloured elements and the white areas representing the blue

Fig. 1.

Fig. 2.

green, O = orange, Y = yellow, V = violet) would be suitable for a method of six-colour photography. In the case of the colour screen shown in Fig. 8, in which the areal division is the same as in Fig. 2, the two colours suitable for a system of two-colour photography are grouped alternately three-fold round every point where six triangles meet; the black areas representing the orange coloured elements and the white areas representing the blue

Fig. 3.

Fig. 4.

coloured elements. In the three-colour screen depicted in Fig. 5, equal sized equilateral triangular unit areas fitted together without intervening spaces or overlapping, are grouped together to form rhombuses, and round every individual point where three rhombuses meet the three colours employed in three-colour photography (R = red, B = blue-violet, G = green) are represented once, whereas round the remaining centres, where six rhombuses

Fig. 5.

Fig. 6.

meet, each of these colours is represented twice, the same colour lying opposite each other. It is also possible in addition to the coloured elements arranged round each individual point where the unit areas meet to have colourless, transparent, or opaque, white, or black elements respectively, or combinations of these represented. Other divisions of the colour screen are also possible, e.g., rhombuses might be formed by the intersecting two series of parallel equidistant lines at an angle of 60 degs. each other, and round each individual point where four such rhombuses meet either two colours might be represented alternately

ing twice, or four different colours once, or three different coloured elements might be represented in combination with one colourless transparent, or opaque, or white, or black element respectively. If the screened surface is upon a glass or other transparent support, the screen can be used placed face to face upon a suitably prepared colour-sensitive plate for taking a negative, or for viewing in colours the positive copied from such negative. When the screened surface is required upon paper or similar material upon which printed impressions may be made, a screened relief surface may be employed for the production of polychrome prints by means of a photo-mechanical process. For the production of such colour screened paper, a printing block with the screen form represented in Fig. 3 may be employed in which the white hexagons must be considered as standing out in relief. Fig. 4 represents the paper surface after

Fig. 7.

Fig. 8.

the printing of the first colour, in which the black areas represent, e.g., the red unit areas. In order to print the other coloured elements the same printing block as Fig. 3 can be employed, the relief areas being stained with the corresponding inks in succession, and by a lateral displacement of the block printed in register so that another series of hexagonal areas shown in Fig. 4 is covered at each printing, until the whole surface has been covered with coloured elements as shown in Fig. 5. In the same way a printing block in the screen form of Fig. 7 may be employed for the production of a colour screen as in Fig. 6, the black unit areas being those in relief. Fig. 9 shows another form of screened printing block (in which the rhombus elements shown in black must be considered in relief), which, by turning at an angle of 60 degs., and adjusting in register after each colour printing, can be employed for the production in three printings of a colour screen as in Fig. 10. The paper colour screens which have been described may be usefully employed

Fig. 9.

Fig. 10.

for the production of two or more coloured pictures by means of one of the ordinary photo-mechanical printing processes. A printing block or stone is prepared in the usual manner from a negative of the subject to be printed in colours taken through the corresponding glass colour screen upon a panchromatic plate, and the block printed in black over the paper colour screen superposed exactly in register. Each colour spot will be shaded down more or less with black, or remain entirely uncovered just in proportion to the required action of that particular colour at the point in question. By this method it is possible to obtain finished colour prints in a very short time, as the coloured screened paper may be kept in stock in large quantities, and practically only one printing has to be considered. When the colour screen is employed for taking negatives, it can, of course, be printed upon glass or other transparent support, and the sensitive emul-

sion then coated upon the screen surface, the plate or film being exposed from the back through the screened surface. The method of printing on film may be the same as that for printing on paper. In the case of glass, however, I adopt the following process:—A suitably reduced and sharp negative is taken upon a sensitive plate. From this negative three positives are printed upon bichromated gelatine surfaces, one of the gelatine supports being glass, the other two celluloid or collodion films. After washing out the soluble gelatine the positives are coloured in suitable solutions, e.g., one in red, the second in yellow-green, and the third in violet-blue colour. The celluloid or collodion films are then laid upon the glass plate, and by means of a magnifying glass, brought into register so that the colours are regularly distributed. In this position the films are cemented securely upon the glass plate, e.g., with Canada balsam, and the whole forms the taking screen, which in taking a negative is placed upon a panchromatic plate, the screen surface being towards the plate. From the resulting negative a positive is made, and this positive is viewed through a similar colour screen in the corresponding colours, whereby the photograph appears in natural colours. It is to be understood that by the expression rhombus I mean a rhombus composed of two equilateral triangles, i.e., having the obtuse angle 120 degs., and the acute angle 60 degs. John Henry Smith, 417 Seestrasse, Zurich, Switzerland.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

SCREENS.—No. 12,235, 1906. Adjustable compensating screens for use in photography and in colour-photography. Brasseur.

## New Materials.

"Gevaert Matt" and "Casoidin" Papers. Made by L. Gavaert and Co., Oude God, Antwerp.

The former of these two papers is a collodion printing-out paper specially recommended for gold-platinum toning, but also rendering some very fine tones of a sepia and red chalk character by simple toning with one or other of the precious toning metals alone. The surface of the paper, an extremely fine matt, is one which fits it for the great majority of commercial professional work. Its ease of manipulation, in our not very lengthy experience of it, is on a par with the best collodion papers, and we did not discover any inconvenience as regards curling of the paper whilst in the washing waters and toning baths. The rich black tones obtained with the gold and platinum baths are very satisfactory. For the warmer tones, the prints are treated to a bath of ammonia, and after a brief washing are toned in a diluted platinum bath. For the red chalks, the ammonia bath is replaced by common salt, and the platinum by a gold bath containing borax and acetate of soda. By the way in which it lends itself to these different methods, the Gevaert paper is evidently fitted for the work of photographers aiming at variety in the prints which they issue to their customers.

The so-called "Casoidin" papers is apparently the result of using a preparation of casein as the vehicle of the silver. It prints rapidly, considerably more so than a representative brand of P.O.P. against which we tried it, tones quickly in the sulphocyanide bath, and yields also very agreeable purplish tones in the combined bath. The surface of the paper is a fine delicate matt, resembling that of albumen. In other respects of manipulation the prints are toned and fixed like P.O.P., but are burnished by hot rolling when mounted.

MESSRS. John J. Griffin and Sons, Ltd., have added to the "GOLDON" self-toning paper recently issued, a matt variety, a sample of which we have found to respond satisfactorily to the treatment recommended by the makers, viz., fixation in a strong hypo solution. The paper gives a fine vigorous print; and the agreeable matt surface accords well with tones obtained.

THE "Chromo" (ortho-chromatic) plate of the A.G.F.A. Company, sold in this country by Messrs. Chas. M. Zimmermann and Co., of 9 and 10, St. Mary-at-Hill, London, E.C., has now been issued in a new form—namely, as the "Agfa Chromo-isolar" plate. The name will indicate that the new issue is a plate specially

prepared against halation. It is, in fact, a combination of the chromatic properties of the "Chromo" plate with the anti-halation substratum, which is the distinguishing and patented feature of the "Isolar." The new plate is thus highly fitted for much difficult photographic work, and is, of course, just as suitable for everyday subjects, presenting no special difficulties, as an ordinary plate. Its orthochromatic properties, we find, on renewing our acquaintance with it, to be of a pronounced kind, and to fit for purposes of copying coloured originals, etc. For this latter purpose the makers are now enclosing in each box of plates a gelatine film screen, 3in. square, properly adjusted to the plate.

A new method of stripping and hatching in black and white and colours has been introduced by Mr. T. S. Bruce, the well-known instructor in retouching and allied branches of work, whose many qualifications to be named as a master of his profession must be known to many of our readers. "Stipplette," as the new method is called, imitates—and imitates extremely successfully—the hatch and stipple effects which are usually obtained with the sable brush somewhat laboriously and none too quickly. By the "Stipplette" method, which equally with the sable brush lends itself to the personal control of the artist, the coarsest and finest hatch or stipple is obtained quickly, and the effect can be obtained over the usual wash, aerograph or powder basis. From its saving of time and labour without sacrifice of result, Mr. Bruce's new method is evidently destined to be of the greatest service to the profession who will find it adaptable to present methods of work, quickening them and cheapening production. Particulars of Stipplette are obtainable from Mr. Bruce, at 4, Villers-on-Heath, Vale, Hampstead, N.W., or from photographic dealers.

## New Apparatus, &c.

Jandus Enclosed Arc Lamps. Sold by Drake and Gorham, Ltd., 66, Victoria Street, London, S.W.

These new lamps are advanced by the makers as possessing the special advantages which attach to lamps of the enclosed arc type. They are put forward for portraiture, enlarging, process work, and photographic and process printing, their small size and economical working recommending them for these various purposes. The "Jandus" lamp is made in several sizes for continuous or alternating current, the consumption of current being from one to four units per hour. The expenditure for carbons may be judged from the stated average life of the carbon, viz., twenty hours. The carbons are automatically cut out of circuit when they require renewing. As regards the efficiency of the lamp from the photographic standpoint, the following figures from a circular issued by Messrs. Drake and Gorham will permit of an opinion being formed of its usefulness in the studio. Fully exposed negatives are obtainable in one-fifth of a second at  $f/6$  on a plate of about 250 H. and D., the sitter being 5 ft. from the lamp. For printing from average negatives by contact, on P.O.P., the times of exposure given are from a minute to a minute and a half, according to the distance of the frame from the lamp—12 or 18 in.

Both classes of lamp, for direct and alternating current, are made to take standard voltages of from 100 to 250, the prices being as follows:—Lamp, £4, £4 2s. 6d., and £4 15s. Resistance: £1, £1 5s., and £2. These are for continuous current: the cost of the lamps for alternating current is a few shillings more in each case.

## CATALOGUES AND TRADE NOTICES.

THEODORE BROWN, of Drummond Road, Bournemouth, sends us his new catalogue of stereoscopic apparatus and publications. It contains full descriptions of its producer's stereoscopic appliances, notably of the well-known "stereoscopic transmitter." We notice Mr. Theodore Brown described on one page as "late editor of the 'Optical Lantern Journal,'" whilst on another his name is given as editing our intermittent contemporary. The discrepancy, we hope, does not imply the cessation of our contemporary from appearance.

MESSRS. MAWSON AND SWAN, Mosley Street, Newcastle-on-Tyne,

send us their latest list of aniline dyes stocked by them for photographic purposes.

THE City Sale and Exchange offer free a twenty-four-page closely printed, with particulars of goods, at reduced prices. Cameras and lenses make up the majority of the apparatus which we observe, is listed at distinctly "bargain" prices.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

CROYDON CAMERA CLUB.—Although the season for demonstration and lectures has closed, a large number of members assembled week to hear Mr. A. Arbuthnot describe his new gum process the result of over three years' patient experimental work with various colloids and sensitizers. The paper, which, we are glad to understand, will be shortly on the market, is sensitised by brushing with ammonium dichromate and methylated spirits with the special solution which will be supplied. Drying is complete in ten minutes, or even less, and the paper prints in about the same time in the shade from a fairly dense negative. Development is expeditiously effected, either by a sawdust broth, or by brush. It is claimed for the paper that the user need have no previous knowledge of gum printing, and by following a few simple directions, he cannot possibly fail to secure good results, the uncertainty characteristic of the process having been entirely removed. Only essentials are a reasonably good negative, and an apparently correct exposure. The lecturer stated that simple mechanical development gave practically all the tones and details present in the negative, showing a full range from black to white, with appreciable compression at either end of the scale. He laid stress on this point, as he said there seemed to be an impression on one must necessarily be an artist in order to work the process: at the same time, there was ample facility for the pictorial worker to correct or alter the tone values, etc., by means of a spray brush; the film was very tough, and local development could be resorted to without destroying the textures. With the ordinary gum process, Mr. Arbuthnot said, the parts developed locally frequently an entirely different texture to the rest of the paper. The discussion which followed was mainly confined to the experience of the workers of the club. Mr. Packham said that, judging from excellent prints passed round, the process appeared to be a good one, but he had seen nothing which could not have been produced by ordinary "gum." Of course, if all elements of uncertainty had been eliminated, this would be a very strong point in its favour. Mr. Lepine Smith had tried the process under consideration and appeared to give systematically good results. He regarded it as a great advance on any other single-printing gum method. Mr. Allen pointed out that the shadows were very free from glossiness.

expressed a very favourable opinion as to the merits of the camera, as did Messrs. J. M. Sellors and W. H. Rogers. Mr. Daw produced a print of his, which had received twelve distinct coatings; if the same results could be obtained with one coating as appeared to be the case, it was obviously folly to employ more.

**OUTHAMPTON CAMERA CLUB.**—Mr. C. Daw, one of the prominent workers of the above club, read a paper to the members on Monday, the 18th inst., on the subject of "Individuality in Photography." The writer at the outset expressed the opinion that individual ideas were more possible of attainment in the way of landscape photography than in architectural work, which latter the club members had so strongly taken up. Proceeding to deal exclusively with landscape work, Mr. Daw urged that it was necessary for workers to travel far and wide for effective subjects, that every district afforded material, from which good results might accrue. He urged that the first necessity with all would do work showing individuality was the recognition of the fact that simplicity must be sought, and that the worker should have some definite reason in his mind why he exposed a plate upon a subject. Having found a subject which promised to provide the least some basis for the carrying out of his idea, the worker should not proceed further till he had discovered the best conditions of lighting possible of attainment, and that he must not necessarily be satisfied with natural conditions of sky and atmosphere, even supposing such conditions were represented on his negative, but having his basis he must from other sources complete the picture with details harmonising with his motive. Mr. Daw recommended workers to make sketches, however rough, of the subjects of the subject chosen before making the exposure, so as to be sure that there should be scheme and concentration in the production, and he pointed out that as far as the print was concerned there was no necessity to employ any particular method or system, but that for the enthusiastic worker who had a definite purpose, the process with which he was best acquainted was the best for him to use. The keynotes of Mr. Daw's paper were the demand, first, for simplicity of subject, and secondly for deliberation and study in his effort to make others see what the worker therein. A very helpful discussion followed, and Mr. Daw was heartily thanked at the close.

## News and Notes.

**MR. J. J. ROUSE**, of the well-known Australian firm of Baker & Rouse, is at present paying a visit to Europe, and is spending a few weeks in London, during which time he is interesting himself in photographic manufactures for the Australian market. Letters may be addressed to Mr. Rouse at the Hotel Russell, Bloomsbury, London, W.C.

**'SANDERSON' CAMERAS.**—In commenting upon the new "Sanderson" booklet of Messrs. Houghtons, Ltd., last week, we should have mentioned that Messrs. Harrods, Ltd., have on show at their premises in Brompton Road, a special "Sanderson" exhibition. This consists of a large collection of "Sanderson" cameras of all patterns, sizes and finishes, and a collection of work done with the "Sanderson" camera. Mr. E. H. Carpenter, Mr. Aubrey Harris, and other well-known amateurs. The exhibition thus affords an opportunity of seeing a large number of "Sandersons" under the most favourable conditions. MANY of our older readers will learn with regret the death at the age of forty years ago of Mr. Russell Manners Gordon. Mr. Gordon's pictures were well-known in the sixties, and very excellent they were. They were all produced on dry collodion by a process which he himself devised. The deceased gentleman was seventy-seven years of age, and left property value £12,682.

**THE SCOTTISH SALON.**—The Board of Selection is composed as follows:—Messrs. J. Craig Annan, Glasgow; W. Crooke, Edinburgh; Patrick Downe, R.S.W., Glasgow; Alexander Keighley, Yorkshire; and James Patrick, Edinburgh. Messrs. Craig Annan, Crooke, and Patrick have served already on the board, and the other two names

represent a new procedure in its formation, the introduction of a well-known artist and photographer from "furth" of Scotland.

**ROYALTY at the Kodak Exhibition.**—The Prince and Princess of Wales paid a visit on June 14 to the Kodak Galleries, No. 40, Strand, where is being held an exhibition of photographs illustrating the recent visit of their Royal Highnesses to India.

THE new premises of Mr. F. H. Fry, the well-known enlarger at Frisian House, 5, Highbury Grove, London, N., are shown in the

accompanying photograph. Mr. Fry has installed the most complete plant for the production of enlargements and other trade work.

THE West of England Manufacturers and Industrial Exhibition to be held at Plymouth in October and November, includes a photographic section in which prizes and medals are awarded. The prospectus is obtainable from the Secretary, A. D. Breeze, 41, Union Street, Plymouth.

**THE FINGER PRINT SYSTEM IN GERMANY.**—The "Times" reports some interesting statistics illustrative of the efficacy of the finger-print system in detecting criminals in Germany. By means of a collection of 65,948 impressions some 3,000 persons were identified during 1905, a result comparing very favourably with that obtained by the old-fashioned system of relying upon photographs, since a collection of 27,050 portraits, consulted in 1,716 cases during the year, enabled only 145 criminals to be recognised. The unerring accuracy of the more modern method seems to be recognised by the law-breakers themselves, for it is stated that in many instances in which a false name had at first been given the mere production of the apparatus was sufficient, before any impression had been taken, to lead the suspects to abandon their efforts at concealment and to confess their identity.

"THE Morning Post" warns its readers of the circulars sent out by Tanqueray, of Paris, offering a "free photo-enlargement." Letters of victims continue to reach the "Morning Post," and it is therefore well to repeat our contemporary's repudiation of a testimonial issued by Tanqueray in the shape of a letter by "Lindfield Brookes," purporting to have appeared in the "Post." These flights of fancy are what we are accustomed to from M. Tanqueray, and we should have thought that all our readers, at any rate, would have taken them at their proper value, i.e., nothing. Yet only a few weeks ago a gentleman asked us to publish his indignant protest that "Truth" should grant its support to the Parisian frauds. Apparently M. Tanqueray's colossal bluff is gulped down by people who ought to know better, yet it is surprising that any person should exist blind to such frauds.

**THE R.P.S. FELLOWSHIP.**—The following have been elected Fellows of the Royal Photographic Society:—F. Martin Duncan, Harold Hood, C. G. Zander, and G. H. Crabtree.

**SUICIDE of a Photographer.**—Mr. Fred Good, photographer, Burton-on-Trent, died at Rugeley last week from poisoning. The deceased, who was well-known throughout Staffordshire, was on a cycle tour when he purchased some perchloride of mercury, stating that he wanted it for photographic purposes. He went into a restaurant, and after breakfast he told the proprietor's wife he had

taken poison and asked for a doctor. He had suffered from nervousness, and left a note stating "Like a decayed tooth, he was best extracted."

**THE Artistic Copyright Society.**—This society, of which Sir Lawrence Alma Tadema, R.A., is president, have just issued a circular from 39B, Old Bond Street, W., in the course of which they say that the energies of the committee have been fully occupied with the consideration of the new Artistic Copyright Bill, and with corresponding or conferring with members interested in special points dealt with by its provisions. At the recent annual general meeting Mr. Edwin Bale made a short statement as to the position of the Bill, and explained that, with the exception of three points, the requirements of the members of the society and of those interested in copyright had been reconciled. Those three points had still to be considered; but only one of them was of the first importance. That was a question between the Artistic Copyright Society and the Newspaper Society, as to dealing with sketches sent to illustrated papers. A conference had been suggested between the two societies, and as the members of both were anxious to arrive at a satisfactory solution, it was hoped that very soon the point would be settled. The Bill is now in the hands of Mr. Scrutton, K.C., for final revision, and as soon as this is completed, copies will be circulated among the members.

The above paragraph from the "Times" of Tuesday last no doubt represents the tenour of the circular issued by the Artistic Copyright Society, which body, we can easily suppose, is satisfied with the Bill as it now stands. But unless very material changes have been made in it since we reviewed its terms in our issue of January 19 and February 2 last, we do not anticipate any support of the Bill in Parliament, and we certainly do not envy Mr. Scrutton his task of "finally revising" the tangle of ambiguities and contradiction which, as we have shown, crop up in almost every clause of the Bill.

The competition arranged by the Birmingham Photographic Company, of Stechford, for prints on "Criterion" paper is booked to close on July 15, and is already being largely responded to by amateurs workers. Dealers about to stock the firm's productions should consider the present time a favourable opportunity.

**THE Word "Photography."**—Those who read Dr. Murray's criticism of the writings of certain photographic historians will be interested to hear that the forthcoming portion of the Oxford Dictionary is a double section, and takes Vol. VII., O-P, as far as piper. Dr. Murray notes that the group of photo-words are with difficulty compressed into fifteen columns, and number no fewer than 240, all except three being of the nineteenth century, and all except six, consequent upon the introduction of photography in 1839.

**THE Norwegian Coronation.**—Mr. Robt. W. Paul informs us that his operator has gone over to Norway to procure animated pictures of the Coronation of King Haakon, which takes place at Trondhjem on Friday, June 22. Special facilities and unique positions have been granted to him, and, weather permitting, it is hoped to secure an unparalleled series of pictures of this function.

## Commercial & Legal Intelligence.

**COMMERCIAL Photo. Company, Limited, Staveley, Westmoreland.**—Debenture registered May 29, for a sum not to exceed £2,000; charged on the uncalled capital and the assets.

**SALE of Improper Postcards.**—The Preston Borough magistrates last week made an order for the destruction of 942 improper postcards seized upon the premises of R. C. Elliott, Moorlane, and ordered the detention of twenty others in view of possible further proceedings. The defendant pleaded that he thought he was keeping within the law. A great many of the postcards were actually copyrighted, and their sale in Blackpool, Manchester, and other places had not been interfered with. The Bench, however, considered the whole of the postcards were improper.

**A MIDLAND Bankruptcy.**—The affairs of Arthur Henry Seeley Draycott and John Arthur Draycott (trading as the Draycott Gal-

leries), photographers and dealers in works of art, carrying on business at 138, The Parade, Leamington, and also at 64 and 65, New Street, Birmingham, came before the first meeting of creditors' week at the offices of the Official Receiver (Mr. A. S. Cully), debtors ascribed their failure to "loss with Draycott (Limited), with shares, heavy expenses, and want of capital." John Arthur Draycott commenced business in 1881 as a photographer at Sun Coldfield. He was without capital, and after trading for about 10 years he executed a deed of assignment, his liabilities amounting to about £200. A dividend of 6d. in the pound was paid. In February, 1901, when he was trading in Walsall, New Street, Birmingham, Northampton, and Leamington, he transferred the assets to a company called Draycott (Limited), which was formed in that year with a nominal capital of £20,000. The company undertook to take over the trade liabilities, and the debtor received 8,995 shares, giving him an undertaking not to trade within one hundred miles of the town mentioned. Shortly before the date the debtor lost £1,675 through the failure of a cycle company, and he had to borrow money to discharge certain guarantees that he had given on behalf of the company. He remained with Draycott (Limited) as managing director until November, 1902, when a receiver for debenture holders was appointed, and the estate was realised on their behalf. In July, 1905, the debtor made arrangements with his son, Arthur Henry Seeley Draycott, who was a photographer's assistant, to purchase the business at 138, The Parade, Leamington, and they commenced trading there, under the style of the "Draycott Galleries." The business was managed by John Arthur Draycott, and his son was engaged in a situation until November, 1905, when he went to Leamington to assist his father. Shortly before that date a branch shop was opened at 64 and 65, New Street, Birmingham. On March 2 last a deed of assignment was executed by Arthur Henry Seeley Draycott, and Mr. J. W. Blackham was appointed trustee. The landlord distrained at the Leamington shop for arrears of rent, and sold on April 21, realising £15. The unsecured liabilities include £780 ordinary trade debts, £110 charges, and £3 3s. auctioneer's costs. The case being a summary one, the Official Receiver was constituted trustee.

**BANKRUPTCY at Torquay.**—A meeting of creditors of Alfred Richmond Maytum, living at Formby Avenue, and carrying on business at 2 Abbey Road, Torquay, as a photographer, was held on June 14 at the offices of the Official Receiver (Mr. A. E. Ward), at Exeter. The debtor's statement of affairs showed that there was owing to twenty-two unsecured creditors £245 16s. 6d., and to one creditor fully secured £900. The assets were estimated at £41 16s. 10d., leaving a deficiency of £204 16s. 10d. The cause of failure alleged by the debtor was "misrepresentation of the value of the business at Torquay purchased by me in October last. I attribute my insolvency entirely to this." The Official Receiver, in his observations on the case, stated that the debtor filed his own petition in consequence of judgment against him for £50 and costs. He had been in business as a photographer for the past thirty-five years, starting first at Ashford, in Kent, with practically no capital. In October last he purchased his present business at Torquay for £170, on a representation, as he says, that the net profits of such business were £425 per annum. At this time he appears to have had liabilities amounting to about £20, and a capital of £40 in cash, being the balance of sum of £200, for which he had, twelve months previously, sold the photographer's business at Worcester. Sixty pounds was paid to the vendor at the time of the purchase of the Torquay business, of which £50 had been borrowed by the debtor from a relative for the purpose. To secure a portion of the balance, the debtor gave two bills of £50 and £33, maturing respectively in March and October, 1906. In March last the debtor was sued on the first-mentioned bill by a Mr. Banner, with whom the bill had been discounted. The action was defended on the ground that no value had passed from the original holder of the bill to Mr. Banner, but judgment was ultimately given against the debtor with costs. The latter amounted to £33, but have not yet been taxed. The usual order was made. The public examination of the debtor subsequently took place before the Registrar, Mr. J. E. Daw. Replying to the Official Receiver, the debtor said his receipts from the business did not average £3 a week, out of which he paid two assistants' wages, house rent, rent of shop, and had to live. He had sold his interest under his mother's will. Questioned by Mr. McIntyre, of London, for creditors, debtor admitted

letter he wrote to the person from whom he purchased the business to the effect that some money was due to him under all of his mother, and that a quarter's instalment was not quite. He considered a monstrously excessive value was put on the business. It was not correct that he never intended to pay Ackland. Mr. Easterbrook, representing debtor, produced two which were handed over by Mr. Ackland when business was used. Debtor said that he did not know one of the customers names appeared in those books. There was not a single address any of them. The entries were not made by Mr. Ackland's keeper, who told him she knew nothing of them, except an at the end of the second book, which she said was made at Mr. Ackland's dictation. The balance-sheet which Mr. Ackland showed when he was treating for the business showed receipts for the £660. Debtor's first week's takings, after paying certain expenses, was 9s. The examination was concluded. A public examination of George William Austin, photographer, 19, Highbury Place, Islington, N., took place at the London County Court on Wednesday, the 13th inst., before Mr. Justice Giffard. The statement of affairs filed by the debtor showed gross liabilities amounting to £629 15s., of which £505 15s. were due to unsecured creditors. To partly secured creditors £68. the value of the securities being estimated at £60. The liabilities expected to rank against the estate for dividend returned at £514 10s. The assets were estimated to produce £7s. 6d., from which £55 5s. had to be deducted for the claims of preferential creditors payable in full, leaving nett assets at £2s. 6d., and disclosing a deficiency of £450 7s. 6d. The nation was ordered to be closed, Mr. Derham, who appeared for half of the debtor asking no questions, and no creditors were present.

## Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given. We do not undertake responsibility for the opinions expressed by our correspondents.

### A NOTE ON THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—Will you kindly allow me to correct an error which I made in my last week's letter on this subject?  
 $Y_2 = 4 + Y_1 = 2$  should read  $Y_2 = 4$  and  $Y_1 = 2$ .  
 $Y_2 = 2 + Y_1 = 1$  should read  $Y_2 = 2$  and  $Y_1 = 1$ .  
 $Y_2 = 1 + Y_1 = 0.5$  should read  $Y_2 = 1$  and  $Y_1 = 0.5$ .  
 Yours truly,  
 ARTHUR PAYNE.

### THE STATE OF WINCHESTER CATHEDRAL.

To the Editors.

Gentlemen,—The tone of the letter by Mr. F. A. Bridge is exceedingly amusing; doubtless it was intended as such. The point in question is:—I have been incorrectly informed as to the condition of Winchester Cathedral, and these misstatements have been corrected. I should end the matter; but Mr. Bridge opens up quite another line in attacking me as "one of those non-members who are good enough to make suggestions re the management of the Photographic Convention." It so happens that at the special request of the President of the Photographic Convention, I have supplied photographs of Winchester, and illustrated books for his personal use, and it has been a pleasure for me to have been of use to him. I will have Mr. Bridge to digest this little fact, and perhaps before long I shall have professional men again he will be sure of his ground. Yours truly,  
 ALBERT GANDY.  
 I delete from Mr. Gandy's letter a quotation from a private letter, which appears to us irrelevant to his subject. We have done our part in allowing our correspondents to state the facts as they saw them. Winchester Cathedral in correction of the information we first gave, we must now decline to admit the prolongation of a discussion which has become a personal one.—Eds. B.J.P.]

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.O., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- A. Wrigley, 46, Forest Road, Southport. Photograph of Boarding Scholars of the Southport Modern School.
- J. Jackson, Seaton Carew, Aberdare, Glamorgan. Photograph of St. Michael's College, Aberdare.

- P. and B. Clifton, Garrison Studio, Newbridge, County Kildare, Ireland. Photograph of Drummer and Drum Horse, 19th Hussars.

F. H.—We congratulate you. You will see we refer to the matter on another page.

ARC-LIGHTS.—Kindly oblige by advising me on the following. I have an electric light studio 13 ft. by 14 ft. and 10 ft. in height (floor to ceiling). The walls and ceiling are papered white. I am using a Davey arc-lamp fitted in an umbrella reflector (the reflector being 4 ft. in diameter). The light seems to be rather nice and soft, but still I find that all the negatives are very unsatisfactory; each one appears to have an electric light glare about it. Should the walls be white, or some other colour? Is a Davey arc-lamp suitable for portraiture? I find, also, that I cannot take a full-length photo with a 6-in. lens on account of the room being so small. What lens would you advise, as I require a lens to cover a half-plate, and I find that I can only get 8 ft. 6 in. away from the sitter? I must have a lens suitable for full lengths. Your prompt attention to the above will greatly oblige.—W. E. J. W.

The Davey lamp is suitable for portraiture, and should give ample light in a small studio. The size of the umbrella-shaped reflector (4 ft. in diameter) is rather small. It is difficult to say what is the cause of the "electric light glare" you speak of, in the absence of any specimens of your work. It may be caused by insufficient diffusion of the light or by too much reflected light, or by under exposure. White walls are not so suitable as light grey, and you would have the reflected light more under control if the walls were papered a medium grey, and a large reflecting screen were used. The amount of reflected light required varies with the sitter and the style of lighting. You cannot expect to get full-length cabinets. The perspective would be horrible. See under "Ex Cathedra."

SHOP FRONTS.—I have orders to take several shop fronts, but cannot do so, as there is always reflections of opposite shops. Can you tell me a way to stop this? Blocking out is useless. I have thought of having large black curtains, hung on a tripod stand, and a hole for lens. Would this do?—SHOP FRONT.

Usually it is not only the lens, but bright objects in the roadway and across the street which are reflected. The back screen is the best plan if you can get one big enough. We have used one 12 ft. square for this class of work, spreading it out on two 12 ft. poles behind the camera, the bright parts of which were draped. If such a screen will cut out the objects which are reflected, well and good. If not, we suggest that you try flashlight exposures at night if the position permits.

SULPHIDE TONING OF P.O.P.—I am using the ammonium sulphide toning bath for P.O.P. Do you consider the results as permanent as sulphided bromides or as the plain fixed P.O.P.? I find a

difficulty in getting other than a warm tone with the sulphide on P.O.P., as when I continue toning the whites get yellowed slightly, and the print gives the effect of sulphur toning. The water here is very "hard." Would that be the cause? I want to get reasonably permanent prints, but the margin of profit is so cut down here that one has to take advantage of every possible chance of saving. I like the warm tone I get, but some people ask for a colder colour, and the article on P.O.P. mentioned a very cold tone.—D.B.

We believe the prints are equally as permanent as those fixed only, but we should assume that the bleaching and darkening process adopted for bromides will give a more lasting result than that obtained with P.O.P. by the ammonium sulphide process, for the reason that the change is partial in the latter case and complete in the former. Most probably the hard water is the cause of the yellowing from the formation of sulphide of lime which is less soluble, and afterwards decomposes in the film. Try with distilled water for the bath and the first wash water afterwards.

**STUDIO BLINDS.**—A little while ago you very kindly gave me advice about studio erection, and in answer to my query re blinds for top you recommended a light green. My studio face (almost) north, but perhaps it is owing to a fair amount of glass roof. Will you be kind enough to tell me if the enclosed material would answer my purpose to produce the subdued light?—STUDIO ERECTION.

The colour is very suitable, though we should prefer a material with rather closer texture than that of the sample sent.

**ILL-EFFECTS OF METOL.**—Would you advise me, through the B.J., what I could get to prevent my hands developing into sores. I use a great deal of metol developer, and I think that is the cause of it. I have tried several remedies without effect.—WILL TAYLOR.

There is very little doubt that the metol is the cause of the trouble. Many who employ it suffer in the same way as you do. The only certain remedy is to cease to use it, and then the sores will soon disappear. If you still continue to employ it you had better work in finger stalls, or India-rubber gloves, so as to prevent the metol coming in contact with the flesh. Lanoline applied to the sores acts as a palliative in some cases.

**STIGMAT.**—A lens of about  $f/6$  aperture of focal length capable of taking the negative in the first instance is about the most suitable for making enlargements from that negative. Hence the lens suitable for all sizes of negatives would have to be of very considerable focal length, so long, indeed, that the camera extension would be unnecessarily and inconveniently great for small work. The same objection applies, but not with such force, in regard to the use of one lens only for copying.

**VARIOUS.**—1. Is there any journal of cinematography; if so, where could I get same? 2. Also, will sulphide of potassium throw down silver in hypo that has been made up with citric acid and sulphite of soda. I should feel greatly obliged if you would answer this through your journal.—E. L. BARNES.

1. Such a journal is, or was, published by Mr. Theodore Brown, Bournemouth. See our note this week under "Catalogues." 2. Yes, the silver will be precipitated as sulphide.

**POSTCARD.**—1. The white spots are rarely the result of defective manipulation. We should take up the matter and that of the setting-off of the printing with the makers. The latter is certainly due to defective manufacture.

**BROMIDES.**—1. In a reply you gave in the last issue you stated that meta-bisulphite was preferable to use to add to hypo bath for bromides (amidol developer). Will you kindly state why, also proportion to add, etc.? 2. And can you mention a really good book on bromide work only, as a reasonable price?—E. J. M.

1. The metabisulphite is better, as it does not endanger the decomposition of the hypo as does a bath of acetic or citric acid, traces of which may be left in the print when it passes to the fixing bath. The quantity of meta-bisulphite is not very important. About half to one ounce per pint of fixing bath, containing three ounces of hypo. 2. The only books are: "Bromide

Enlarging and Printing," by S. H. Fry (6d.); "Bromide Printing," by Rev. F. C. Lambert, and two books on toning bromides by C. W. Somerville and R. E. Blake-Smith respectively. 3. Fallowfield, 146, Charing Cross Road, London, W. A. B.—We cannot understand how 12lb. of paper can yield 1 lb. of ash. We could not say what weight of silver was present without an analysis. Perhaps the makers of the papers can give you a rough idea.

**A COUPON QUERY.**—I should like your advice on the following. I sent out a canvasser (no wages, only commission) to coupons the same as enclosed, and it appears he went into a firm in —, and they stamped all my print coupons with their own stamp, so that the canvasser could sell them in their district, and so get customers on my ticket. I should be pleased if you could let me know what action I could take against them. I have written them twice, but they have ignored my letters: Your advice on this matter will greatly oblige.—M. B. O.

We do not see that you can do anything. As the coupons were stamped with the consent of your canvasser you cannot make any claim against the firm.

**BEGINNER.**—We believe the print to be on collodio-chloride paper, toned first with a gold bath and then with platinum, as given in the Almanac, 1906, p. 976. Any collodion P.O.P. will answer. **POSTCARDS.**—The stains are due, we believe, to insufficient fixation. Fifteen to twenty minutes is none too long for cards. There is no possible way of removing the stains.

**N. M.**—Insufficient fixation with subsequent light action, or the use of an old fixing bath, particularly one that has been used for developed plates or papers, would at once cause the stains. Occasionally, similar stains are due to allowing the cards to lie on top of the other in the first washing water, and then a preliminary bath of a 10 per cent. solution of common salt will obviate them.

**SELF-TONING PAPERS.**—Will you kindly inform me if I can with safety use self-toning paper for ordinary photographic work, i.e. will it keep colour as well as toned paper? I use the Lux paper, but for unpaid proofs only. It gives beautiful sepia prints and if it will keep colour it would save a lot of time.—J. M. I. Treated with proper precautions there is no reason why prints should not be permanent. The fixing bath should be slightly alkaline, and the prints are all the better for washing before immersion in it. We advise you to select a paper with which these conditions can be observed.

The Bristol Photographic Club.—No. 2 of this club's monthly magazine reaches us, and contains, we see, an article upon "Artistic Perception," by Mr. Alex. Keighley. It is intended to follow this up by a series of articles from other well-known workers.

An exhibition of photographs of Switzerland by Dr. O. Thurstan Holland has succeeded the house exhibition of Herr Dührkoop's work at the Eberle Street Rooms of the Liverpool Amateur Photographic Association. It will remain open until July 3. Dr. Holland brings together sixty-five examples of his well-known work in Alpine photography, and exhibits also 150 lantern slides. The next house exhibition of the Liverpool Association will be of photographs by Mr. C. F. Stuart.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

First Division of the Court of Session last week recalled judgment of Lord Ardwall, and awarded Mr. William Crooke, Edinburgh, £5 damages against the Scots Pictorial Publishing Company for publishing without leave in "The Society Pictorial" a portrait of the late Sir Henry Irving; but, inasmuch as the defenders had tendered £20, the pursuer was found liable in expenses since the date of the tender. (P. 510.)

The death roll this week includes Mr. A. H. Wall and Mr. J. ... (P. 512.)

Manly's new process ("Ozobrome") of producing carbon prints from a bromide image is described in the patent specification. (P. 513.)

The inability to see the plate on first coming into the dark-room ... (P. 502.)

Colour Photography.—Dr. Albert Norman has communicated to R.P.S. his working methods in making transparencies by the Sanger-Shepherd process. (P. 506.)

Colour Photography. — Herr Novak, of Vienna, has published ... (P. 505.)

The sulphide toning of P.O.P., advanced by some for its cheapness, is shown to be of very doubtful advantage in this respect. (P. 503.)

The advantages of, and apparatus for, wholesale development. (P. 501.)

A method of dealing with negatives which conform fairly closely to an average, is recommended by a contributor, and consists in ... (P. 504.)

We publish the continuation of the papers by Mr. N. S. Amstutz on the properties of engraved half-tones. (P. 507.)

## EX CATHEDRA.

### A Single-Picture Exhibition.

The Professional Photographers' Association have in course of organisation an exhibition something on the lines of that held by the Professional Photographers' Society of New York, of which mention has been made several times of late in our columns. The exhibition will consist of a number of prints, each representing the work of one photographer's establishment, and thus enabling those visiting it to compare notes with their fellows as to what may be done in the presentation of a commercial photograph. The exhibition will be held in the small gallery at the office of "The British Journal of Photography," from October 11 to November 11, that is to say, for a great part of the time during which the Royal and Salon Exhibitions will be open in London. While it will be composed of work by members of the P.P.A. it will be open to all photographers and to the public generally.

### Plate Development in Batches.

As his business increases, the progressive professional finds out that the development of plates singly or in pairs is too slow a method of working, and results in too much time being spent in the dark-room, and too little in contact with clients or in business-making. The development of plates singly also conduces to irregularity or inequality of result, and where exposures are made with reasonable accuracy much more uniform results are obtained by wholesale development. This may be done in various ways. Developer may be placed in a porcelain grooved tank, but we have found that unless very dilute there is a great risk of uneven development, and as dilute developer means prolonged development this method is put out of court. An alternative is to place the plates in a number of small dishes, the dishes resting on a large board operated by a rocking device. This method ensures freedom from damage by one plate slipping over another, but it means covering each plate with developer separately, and the wave of developer caused by rocking is steadier in one large dish than in many small ones. To develop a dozen or more plates in one dish necessitates that the dish shall have a glass or flat wooden bottom or the plates slide over each other, and while this may be at once remedied with ordinary plates, if highly sensitive orthochromatic plates are employed it is not possible to see what is happening, as the dish must be kept covered. From the glass bottom it is difficult to pick up the plates when ready for fixation; the dish is also heavy and liable to breakage, so that in many ways wood will be found superior.

### Wooden Developing Dishes.

For convenience in handling a well-constructed wooden dish is probably superior to anything. It should be constructed of straight-grained, well-seasoned wood. Yellow

pine answers well, but is rather soft, and any strain on the joints is apt to compress the wood slightly and so give rise to leakages. Straight-grained mahogany may be used, at any rate for the sides. Grooved joints are preferable to dovetails for the corners, and every joint should be perfectly tight-fitting and the wood quite dry before joining up. When glued and screwed with brass or copper screws the wood may be saturated with paraffin wax, ironing in the wax with a warm flat iron. If difficulty is anticipated with plates sliding over each other during development the dish may be divided up by means of wooden pegs projecting about three-eighths of an inch. These pegs may be arranged so that two come at the side and two at the end of the half-plate. If slight depressions are made in the bottom of the dish, one for each plate, the finger is able to lift the plate more quickly, and there is not the danger of the sharp corner cutting into the skin as it sometimes does if the nail is reasonably short. The disadvantage of the pegs, which, of course, are glued into position before waxing the tray, is that they limit the use of the dish to one size of plate, but this is a disadvantage which always attends the use of any specialised apparatus.

#### The Crooke- Irving Case.

Photographers will congratulate Mr. William Crooke, of Edinburgh, on what is virtually a reversal of the judgment against him almost exactly twelve months ago. The revised judgment is important as regards copyright in photographs, because, in the course of it, it was made clear that a number of photographs may be taken of a person at one sitting arranged by a third person, and copyrights in certain of them are obtainable by parties other than the party arranging the sitter, provided that the photographer be paid in respect to these photographs. Such a possibility is a perfectly natural one, and there is nothing in the Copyright Act to prevent it, but the suggestion in Lord Ardwall's judgment a year ago was that Mr. Shorter was *prima facie* entitled to all the portraits taken at the sitting, unless it could be shown that Mr. Shorter or Sir Henry Irving agreed to any of the photographs becoming the copyright of the photographer.

#### Factorial Development.

We recently published an article by Mr. A. Lockett which showed that the personal error in working the factorial system is very slight, provided the "dark-room" is well lighted. There is, however, a source of error not mentioned in the article, that forms an insurmountable difficulty to many who work under the conditions that have normally to be put up with. A correspondent writing to us on this subject says:—"If I make an exposure by daylight, and then proceed to the dark-room to develop the plate, I find it not merely difficult but quite impossible to judge the time of appearance. The light I use is a flat flame gas jet behind two thicknesses of ruby medium of 10in. by 8in. area. When accustomed to the light I can see easily enough, but when I come in from daylight, the first plate that I develop is practically invisible while in the developing dish. The second plate is more easily seen, but I can never venture to judge the time of appearance from it. Any attempt to do so only leads to a series of false alarms which are terminated by the sudden discovery that the image is fully out. When I arrive at the third plate I can observe the time of appearance with considerable accuracy, but, by this time, the first plate dealt with is sufficiently fixed to bear examination, and if this proves to be satisfactory I simply proceed on the same lines with the rest of the exposures, and do not worry about time of appearance at all. As most of my development is done in the daytime, immediately after the exposure, I am seldom in a position

to employ the factorial system at all, and probably many others have the same difficulties to contend with. Possibly the time required for the eyes to become accustomed to the red light varies with different people, but it is evident that there is a certain period (about ten minutes in our correspondent's case) during which the estimation of the time of appearance is either impossible or unreliable. There is a very probable source of error here and while it may be eliminated by waiting in the dark room until the eyes become acclimatised, we should prefer to spend the time in development and risk spoiling a couple of plates. These are developed for a fixed time, and ten minutes we can judge from the first plate whether the time is correct or not, and then proceed with the rest accordingly. Those who develop only at night, or who spend all their time developing, can, of course, use the factorial system without difficulty, but those who work under the conditions we have considered should always bear in mind the possibility of error from a cause which we cannot remember to have been noted by Mr. Watkins or any of his converts to factorial development.

#### The Surface of Portrait Photography.

Quite apart from questions of likeness, light and shade; contrast or brilliant or pose and general arrangement, the factor in the appreciation with which professional work is met is found in the surface of the photograph. This naturally varies somewhat with the class of customer, but the size of the portrait, but, generally speaking, it may be found that the public taste runs to a semi-matt surface. To a great extent this quality of surface is the reason for the popularity of matt collodion papers and of some of the newer gaslight papers. It is the experience of some professional workers that the A.A. platinotype paper does not possess a sufficiently smooth surface, and they use such prints through a burnisher slightly warmed, so as to assist in straightening the cards. To many, of course, one of the charms of either smooth sepia or black platinotype is the velvety character of the surface, and care should always be taken to ascertain, not necessarily by a direct question, which kind of surface is preferred by customers ordering platinotypes. With carbon there is the choice of double transfer from the ground opal surface, or from a flexible temporary support, and of single transfer on almost unlimited selection of papers. From an artistic point of view the single transfer surfaces are most pleasing, and next to these the flexible support, the prints being wetted after trimming, so that the glaze is almost lost except in the shadows, where it gives a richer effect. Carbon prints, especially if dark, when stripped from ground opal glass tend to have a heavy or leathery appearance in the shadows. This depends to some extent, it is true, upon the character of the negative, particularly in the matter of shadow detail, but it is always a danger to be guarded against.

#### The Convention.

There is little more to add to the notice of the Photographic Convention of the United Kingdom which we have published during the past few weeks. We hear that a contingent from Paris is coming to Southampton, and that so far as the United Kingdom is concerned the attendance promises to be the largest for some years past. As befits its venue in such a yachting centre as Southampton, the Convention, it is understood, will not encourage, in fact it will discourage conventional hot town attire of the frock coat and the tall hat. Cool summer clothing such as the tourist dons for his comfort in hot weather will be adopted, it is hoped, at ordinary meetings of the Convention, the dinner of the Wednesday being the only occasion when "dress" is

rigueur. This notification of what we believe is the  
ing and intended practice of many Conventioners may  
haps be welcomed by some as saving them anxiety in  
cting their wardrobes.

w Our  
rders  
rk!

Photographers who are trying to raise  
the tone of their profession must have  
felt disgusted with a paragraph which  
at the round of the press last week under such headings  
"A Photographer's Pillory." It recorded the act of  
photographer in the Home Counties towards a sitter  
alcitrant in the matter of payment. The photographer  
hibited in his window a photograph of the young man,  
aching to it the inscription:—

THIS IS THE MAN WHO PUT HIS HAIR IN CURLS TO HAVE  
HIS PHOTOGRAPH TAKEN, AND THEN CAN'T PAY FOR THEM."

spite the grammatical evidence in its favour, we were  
otant to credit the incident as related in the news-  
pers, but on inquiry we find it correctly described. We  
e further discovered that the photographer is, or was,  
arpenter, a fact on which he may congratulate himself,  
his craft in working wood may shortly afford him the  
ans of livelihood when the opportunities of engaging  
a more cultivated profession have been withdrawn. We  
afraid the entrance of artizans into the "photographic  
fession" is attended with even worse results than might  
expected, not to say hoped. The case of an individual  
o followed the vocations of photographer and sweep  
res elsewhere in this week's Journal.

## SULPHIDE TONING OF P.O.P.

Readers of our "Answers to Correspondents" columns  
y have noticed, there is frequently manifested on the  
rt of our inquirers the desire for a process of toning  
ich dispenses with gold chloride or other expensive  
stance. Candidly, we are not at all in sympathy with  
h methods, for we have reason to distrust if not to  
ay the claims which have been made from time to time  
"goldless" toning preparations. "Sulphur toning"  
n an acidified solution of hyposulphite—stands self-  
ndemned, in our experience, as a method of producing  
nts which will last, though we occasionally hear of  
se who do not share this view. A letter in our pages  
ly a few weeks ago is an instance. Our object now,  
wever, is not to refer to "goldless" processes in general,  
t to that in particular in which the toning is done with  
sulphide.

In the early days of silver printing the toning bath  
quently employed was an acidulated solution of hypo,  
o which the prints were immersed with or without wash-  
g; the result was actually that the prints were toned  
th sulphur or sulphide compounds. The process did  
t give permanent prints, and there was considerable loss  
intensity.

Hardwich, in 1856, was one of the first to investigate  
e action of ammonium sulphide on fixed silver prints,  
d he stated that the brick-red image turned first brown,  
n brownish black, and finally pale yellow. Sutton, in  
67, also investigated the subject. He described the same  
anges, and expressed the view that as the whites kept  
re this was a proof that there was no silver left in the  
ites of the image, a view which was combated experi-  
mentally by Carey Lea.

Quite recently there has been a recrudescence of the  
ea of utilising the action of a sulphide as a toning agent.  
his may be due to the fact that the sulphide toning of

bromide prints has been brought so prominently to the  
front, or, as indicated by a query in our last issue, it may  
be the direct result of keen competition and cut prices.  
At any rate, the practice of applying to P.O.P. a process  
which has proved extremely valuable in the case of  
bromide and gaslight prints has evidently been on the  
increase of late, and we have made a few experiments  
to determine as far as possible the safest procedure to  
adopt.

We may assume that the particular sulphur and silver  
compound which should be formed is the well-known mono-  
sulphide  $Ag_2S$ , which is of a brown or blackish-brown  
colour, and is, as prepared by chemical precipitation, a  
most stable salt. It can be formed by the action of a  
sulphide on metallic silver. There are, of course, many  
other sulphides and oxysulphides of silver, all of which  
are very unstable and easily decomposed by the action  
of damp air and light. The formation of these must be  
as far as possible avoided, therefore the very first thing  
we have to do is to ensure that our print contains no  
disturbing compounds. This is not such a difficult matter  
to do, provided we set about it in a systematic way.

The prints should be immersed in a solution of salt  
and water, so as to convert the whole of the soluble silver  
salts into chloride, then thoroughly washed to free them  
from any acid or acid salts used as a preservative for the  
emulsion. In fact, the safest plan would be to use for  
the first bath a solution of salt and washing soda, and  
then wash thoroughly. Thus the print would consist of  
nothing but the light-affected silver salts and silver  
chloride in the vehicle.

Perfect fixation is a *sine qua non*. The fixing bath  
must therefore be freshly made—that is, must not  
have been previously used. The prints must be allowed  
to remain in this and kept continually on the move for  
at least a quarter of an hour, and then rapidly washed  
for a few minutes, and again immersed in another and  
fresh hypo bath, so as to ensure the perfect solution of  
the hyposulphites of silver. The prints must now be  
thoroughly washed, so as to entirely eliminate all silver  
hyposulphites, and they are ready to be toned.

There must be considerable over-printing, as not only  
is there considerable loss, particularly in the high-lights,  
but unless a fairly rich image is obtained rich tones are  
difficult to get, and this is apparently more likely to  
happen with some commercial papers than others. There  
is also another disturbing factor. In cases in which a  
tinted support was used the colour, by the action of the  
sulphide bath, was not only entirely bleached, but was  
actually converted in one case into a pale apple green.

The next point to determine was whether it would be  
possible to use sodium sulphide instead of the ammonium  
compound, as the former is more stable and equally as  
handy. In comparative experiments on prints on the same  
papers and printed under squares with densities ranging  
from bare glass to 3.01, that is, opacities from 1 to 1.024  
in geometrical progression, no difference could be detected  
in the action of the two sulphides except that the ammo-  
nium was slightly more rapid.

The amount of sodium sulphide that should be used is  
apparently dependent on the temperature of the solutions  
and whether distilled water is used or not. The average  
quantity is apparently about five grains to the pint. With  
this strength rich tones are obtained in from fifteen to  
twenty minutes. Quickening the action by increase of  
sulphide certainly produces blacker tones in the shadows,  
but the lighter half-tones assume an unpleasant greenish  
tinge, particularly with collodio chloride papers.

After the prints have been toned to the desired colour  
they have to be thoroughly washed, and here a little

difficulty was met with which may or may not be of importance. One of the most delicate tests for an alkaline sulphide is sodium nitro-prusside, which gives a magnificent purple colour with an alkaline sulphide. Prints washed in successive changes of water and in running water gave not the slightest trace of this colour when the drainings were allowed to fall into a test tube, yet a drop of the nitro-prusside solution gave a distinct coloration in the whites of the prints. As the solutions were made with distilled water, it at once seemed probable that the washing water, which was hard tap water, had precipitated some of the comparatively insoluble calcium sulphide in the film. This idea seems borne out by the fact that sodium sulphide added to the tap water gave in a very few minutes a very cloudy mixture, which rapidly turned yellow, pointing to the presence of some metallic impurity.

As to the subsequent action of precipitated calcium sulphide in the image-bearing film we are not prepared to speak definitely, but should it be harmful it would necessitate the use of distilled water for all operations, which would at once place this process out of court in comparison with gold toning. It might be used with ordinary water for very cheap work, the subsequent fate of which was not of the slightest moment.

Experiments were also made in which the prints were bleached with bromine water—also with ferricyanide and a halide—and then submitted to the action of sodium sulphide. We followed out, in fact, the process adopted in the sulphide toning of bromide prints. Others previously toned with gold, with platinum, and gold and platinum were also treated by the two methods, but with extremely unsatisfactory results in all cases. The tones

obtained were hideous, and verged on a dirty green sepia in the high lights and lighter half-tones and green blacks in the shadows.

The process as it is to be worked may thus be summarised:—

- (1) Immersion for ten minutes in salt, 1 oz.; soda carbonate cryst., 1 oz.; water, 20 oz.
- (2) Washing for fifteen minutes.
- (3) Fixation for fifteen minutes in hypo, 3 oz.; water 20 oz., made fresh, followed, as a safeguard, by a second fixation in a fresh bath for five minutes.
- (4) Washing for twenty minutes.
- (5) Toning in ammonium sulphide, 5 drops (or of sodium sulphide, 5 gr.); water 20 oz.
- (6) Final washing for fifteen minutes.

The conclusion to which anyone trying the process will come will probably be identical with our own, namely that simple treatment of the well fixed and washed print with sulphide is capable of giving very fair brown and purple brown tones, but that to produce these results uniformly the routine must be conducted with considerable exactness, and it must not be supposed that the process can be applied with equal success to all brands of P.O. Furthermore, each individual must consider whether, after all, the cost of the gold is such as to make the process worth while. Perhaps we do not appreciate as keenly as we might the need of cutting down every item of expenditure in cheap work—we certainly cannot sympathise with the production of work at these miserable prices—yet we doubt if the sulphide “gold-less” process is any cheaper in the end than orthodox gold toning, in its most commercial form, the combined bath.

## PRINTING BY PILOT.

The Americans have reduced labour-saving to a science, and are willing to accept any idea whether new or old so long as they can save time in working and incidentally put money in their pockets. The photographer is not behind the rest of his countrymen in this particular, and as he is more go ahead than his British cousin, he has many labour-saving dodges in his workrooms.

Dodges that have originated in the old country, and have perhaps been forgotten for a decade, are perfected and run for all they are worth in America. One of the best examples of this kind came before my notice some short time ago, and as it is very useful where large quantities of negatives are handled, it may be worth while describing it, and at the same crediting the old country where it was worked many years ago, and for all I know may be in use to-day.

With large quantities of negatives to be printed from, a great portion of the work lies in examining each print, perhaps two or three times, before it is ready to be taken in. If it were possible to use one negative as a pilot so that when this one negative was fully printed the whole batch could be brought in, it would mean a great saving of time and money. There are many difficulties to be faced, negatives having a way of being either too thin or dense, flat or brilliant; some taking a tenth of the time to print compared with another which might have been exposed on the same day under different conditions. The professional photographer, alas, cannot choose his time and light for his work, and even if he could it would be impossible to make every negative of a given density; therefore, if the mountain will not come to Mahomet he like a wise man goes to the mountain. Whilst admitting it is not possible to get all negatives of the same density a good operator will keep them within reasonable bounds and ingenuity will do the rest.

For printing by the method I am about to describe a special bench is required. It must be made at the side of the printing-room, as we shall require the use of a certain amount of daylight. Beneath it a hole about 2 ft. square is cut in the side of the printing-room

under the bench, and a reflector made of a few boards covered with white paper is fixed under the bench from the bottom of the hole to the front of the bench. Then in the bench itself, over the reflector, are cut two holes each large enough to take a half-plate. In these two holes we place two pieces of finely-ground glass, and our apparatus is complete.

The following drawing will perhaps make the explanation clearer.

A is the side of the printing-room, which should be lit by A<sup>2</sup> a window of yellow glass. B is the top of the bench. C is the reflector. 1 and 2 are the two holes.

The idea is to bring all the negatives for the day's work up to the densest, following the nautical maxim that the speed of the fleet is judged by the slowest ship. Therefore we pick out the densest negative to act as a guide or pilot. This we put over hole No. 1. We take the next negative of the batch, place it over hole No. 2, a

pieces of clear celluloid with which we have provided ourselves, we add piece after piece until the density of the pilot is equalized, and so on until all the negatives are brought up to equal density.

No doubt there is some careful judgment required to match the negative, but this is not an unsurmountable difficulty, and after little practice a practical printer will be able to tell without doubt how many pieces of celluloid are required.

There are no further difficulties to overcome. Unskilled hands load the frames and put them out to print. Care must be taken no time is lost in getting all frames out as near the same time as possible. All the foreman has to do is to examine the pilot negative, and when he considers that the print is printed to the right

depth all the frames are brought in commencing with the first frame that was put out.

The advantages of this method are many and obvious. One skilled printer and one or two apprentices could manage large quantities of frames with ease. The pilot print could be toned or developed, as the case might be, and correct printing assured before the frames were unloaded. For platinotype and carbon printing its value is increased tenfold. Flashing by exposure during examination would be obviated, uniformity obtained, and work carried out with clockwork regularity.

This is not theory, but a method that is in daily use, saving much needless work, and reducing the risk of uneven printing to a minimum.

W. E. DUNNE.

## FOREIGN NOTES AND NEWS.

### Rapid Filters for Three-Colour Work.

Professor Novak communicates to the current number of the "Photographische Korrespondenz" the following methods of making a set of rapid filters, using dyes prepared by Meister Lucius and Bruning:—

Rapid filter green ..... 1.75 gms.  
Water ..... 1.50 ccs.

In 100 ccs. of a 6 per cent. solution of gelatine add 20 ccs. of dye filter; of this dyed gelatine 7 ccs. should be coated on 100 sq. cm. glass, and two such screens cemented together. The stock solution of dye must be freshly prepared, for if kept it turns brown. The red filter is prepared as follows:—

Rapid filter red I. .... 1 gm.  
Water ..... 40 ccs.

In 100 ccs. of a 6 per cent. solution of gelatine add 20 ccs. of dye filter; of this dyed gelatine 7 ccs. should be coated on 100 sq. cm. glass, and two such screens cemented together.

Novak states that these filters approximately transmit 33 per cent. light than the old König filters, and that the ratio of exposures of a cloudy sky is as 1:2:2. The splitting up of the colours by new filters is said to be very satisfactory.

### A New System of Colouring Prints

Herr Pietzner, of Vienna, has patented a new process of colouring prints, and some results are very highly spoken of in the German papers. It can be applied to photographs on linen, ivory, paper, leather, porcelain and glass, and the results are said to be characterized by the wonderful fineness and fascinating effect, such as has not been attained by any other process. Apparently there are no practical difficulties, and the materials are shortly to be placed on the market.

### Three-colour Photographs of the Solar Eclipse.

Professor Mengarini, of Rome, took several negatives by the three-colour method of the total solar eclipse of August 30, 1905, and at a recent public lecture in Milan some of the results obtained were shown and created enormous interest. It is stated that the corona was shown in all its finest shades of colour.

A VERDICT of "Suicide whilst temporarily insane" has been returned at the inquest on the death of Mr. F. Good, of Burton, whose decease was announced last week.

MR. PETER MAWDSLEY.—The sum of £28 12s. 6d. subscribed almost exactly one year ago by a number of our readers in response to our appeal on behalf of Mr. Mawdsley has been handed on to the recipient by our publishers at regular intervals, the concluding instalment having been paid last week. In writing to acknowledge the receipt, Mr. Mawdsley asks us to transmit to those by whose kindness he has benefitted his heartfelt thanks. For the past two years he has been confined to his bedroom, but he is grateful to those who aided in relieving the conditions under which he is forced to live.

### A New Method of Photographing Coins.

Dr. E. Demole comments upon the usual method of obtaining good photographs of coins and medals, that is to take a cast, colour, and photograph it. He suggests the following method:—Place the coin or medal between two sheets of white glazed card, which should be very thin and dampened. The whole should then be placed between two pieces of thick felt and then subjected to strong pressure in a copying press. After a short time the impression of the coin is perfect. The impressions should then be lighted from one side and photographed not on to a plate, but on to smooth glazed bromide paper. The result is a negative, which is rather weak, but the reversed lettering is again reversed in the negative, and the side lighting having left the surface in comparative shadow, the face of the medal remains white or grey, as though all those parts in relief had not been illuminated, whilst the illuminated parts remain black. The result, although a negative, has all the characteristics of a positive. The lighting is certainly a little stronger and unnatural, but it is quite sufficient to give all the necessary details of the coins. The real negative is, of course, the impression on the paper, and the negative made by the lens is the positive. The catalogue of the coins of the Numismatic Society of Geneva, which number some thousands, has been illustrated by this process.

### A New Blue Toning Bath for Bromides.

ACCORDING to "Das Bild" the following modification of the ordinary method of toning bromide prints blue is said to give extremely brilliant results. Two stock solutions are required.

A. Potassium ferricyanide..... 8 parts.  
Water ..... 1,000 parts.  
B. Ammonia iron alum..... 10 parts.  
Hydrochloric acid..... 10 parts.  
Water ..... 1,000 parts.

For use mix—

Solution A. .... 100 parts.  
Solution B..... 200 parts.  
Water to..... 1,000 parts.

There is very little tendency to stain, and the shadows possess a transparency not attained by any other methods.

A NEW Professional Society in Philadelphia.—According to the "Photographer," at a meeting of the professional photographers held at the Phillips Studio, 1,206, Chestnut Street, on June 5, at 8 p.m., the Professional Photographers' Association of Philadelphia was formed. There were seventeen photographers present, all of whom joined the Association—and in addition there are a number of applications for membership. The following officers were elected:—President, Ryland W. Philips; Vice-President, William H. Rau; secretary and treasurer, H. Allen Krips.

PROFITABLE Photography!—A correspondent writes:—"I was shown some photographs this morning, taken by a photographer in North London. Six cabinets (P.O.P.), mounted, and a whole-plate enlargement on a 12 by 10 P.S. mount—2s. 6d. the lot."

## THREE-COLOUR TRANSPARENCIES BY THE SANGER-SHEPHERD PROCESS.

THE following is the report of the demonstration recently given by Dr. Norman before the Royal Photographic Society. It constitutes the most detailed and authoritative description of the method employed in preparing three-colour slides by the Sanger-Shepherd process of which we know. Dr. Norman, it would be seen, prefers to over-stain and then wash out the surplus. Any fine detail removed at the same time is restored by a brief supplementary staining. No better recommendation of this procedure can be advanced than the magnificent photo-micrographs in colour of Dr. Norman's, to which a medal was awarded at the St. Louis Exhibition.

Dr. Norman said he proposed to deal lightly with the negative and the lantern slide and to spend most of the time on the manipulation of the films, with printing, developing, staining, varnishing, and sealing the slide, and at the end he would show a few slides on the screen. As his methods of working were the same for outdoor or indoor work, he proposed to stain up a set of films in the way he was accustomed to do for photomicrography, and to make a specimen throughout. The subject he had selected was crystals of sodium carbonate. He chose that specimen because it was a good one on which to demonstrate registration of the three images. The specimen was photographed by polarised light, a selenite being used to show the crystals in colour, and with a strong light the exposure given was 25 seconds for the red screen, 1½ minutes for the green screen, and 30 seconds for the violet screen, and this was practically quite correct. He found the new plates supplied by Messrs. Sanger Shepherd and Co. very sensitive to red light, as was shown by the exposure given. He ordinarily used a ruby glass in the dark room lantern with gaslight, and working three feet away from the light he got no trace of fog whatever, but if the plates were held close up to the light the plate quickly fogged all over.

When dry he spotted the negatives if it was necessary, and after that he varnished them. The varnishing was an important matter, as it prevented injury in printing.

The next step was to make a lantern slide from the negative taken through the red screen, and that slide (in black and white at first) had to be converted into a blue colour by means of the solution supplied. He found that with an average negative an exposure of ten seconds at 2½ feet from a fish-tail gas burner would be about right. There was little to say about the slide except that it should not be under-exposed, as under-exposure was a cause of one image overlapping another. A correctly exposed slide should be full of detail and gradation. He had such a slide in his hand. When developed, etc., the slide was bleached in a solution of red prussiate of potash. It was then washed in water for ten minutes or until the slide showed no trace of yellowness, when it was ready to be converted to the blue colour, which was done by immersion in one part of the minus red solution added to two parts of water, and then it was placed in fresh hypo for one minute. The slide had to be washed for ten minutes, dried, and then varnished. A pink and a yellow film had then to be made from the negatives taken through the green and the violet screens.

### Timing the Printing of the Films.

These films may be obtained ready sensitised, and although they will keep a considerable time in the calcium chloride case it is advisable to use them whilst fresh, as after keeping them for only a few days in the case they will begin to get stiff. A sensitised film was placed in the dark room over the negatives in the printing frame, with the celluloid side to the negative, and as a guide to exposure, which is done in diffused daylight, a Chapman Jones Actinometer is found useful. Practically the only numbers used are the 1, 10, and 11. A piece of Solio paper should be used with the actinometer. The correct point at which to stop printing can only be found by experience. On printing the films the image will show only very faintly. The films are developed in warm water, ranging from a temperature of about 90 degrees to 105 degrees Fahr., the temperature depending a great deal on the solubility of the films. The work may be done in the dark room, brightly lighted by an orange medium window, or we may work in diffused light, such as is obtained by drawing down a dark blind in a room, or we may work by weak gaslight. Dr. Norman said he used a deep porcelain dish and filled it with water

at 105 degrees, and immersed the film, leaving it quite still for three or four minutes before examining. Plenty of time must be given to let the surface of the emulsion on the film show signs of solution. Directly the top layer of emulsion has given way we lift the film out and lower the temperature of the water to about 85 degrees, then the film is re-immersed, and if the emulsion continues to dissolve we know that development is proceeding all right. Presently we shall see the details more perfectly, but development must be carried on slowly to get the best results. At a later stage, instead of the emulsion running off with a creamy appearance it will look like milk, and later still the water draining from the film will be very nearly clear. If then the image is not fully developed the temperature must be raised by adding more warm water. It will then be found that the emulsion will again run off the surface till the image is completely developed. If the film is held over some dark surface every detail in the image can be seen. When development is complete the film is placed in a clean hypo solution, 1 in 40, until all the white bromide of silver has been dissolved out, when it must be washed in running water for about half an hour and hung up by clips to dry, or it may be stained at once. Dr. Norman preferred, as a rule, to dry the film first.

### Staining and Assembling.

In preparing to stain up, the first thing was to separate the two impressions, leaving sufficient margin, and in order to distinguish the films a corner should be cut off the one that is to be stained yellow. The two films have now to be stained. The film should be held at the side by a clip and dipped in the dye. It is well to reverse the clip from one side to the other in order to equalise the action of the dye. It is desirable to stain very thoroughly and then wash out the surplus. If the lighter details become too weak in the washing it is of no importance; a second immersion in a weaker solution of dye will restore these fine details. In making up the slide the first film should be one-eighth of an inch narrower than the blue slide, and the second film should be one-eighth narrower than the first film. The films being placed in register and held together with clips these margins must be roughened with a pointed instrument so that the gummed strip of paper which holds all together may adhere firmly. Out of 200 negatives Dr. Norman said he had only one which would not register, and felt sure that in that case it was due to under-exposure in one of the negatives.

### Cementing and Mounting.

The films must then be varnished, and for that purpose special crystal varnish was used. One corner of the film was held by a clip, and as the film is very flexible it is advisable to support it by means of a piece of cardboard held between the fingers. A little of the varnish is poured on at one end and allowed to flow all over. Now these films are hung up and left to dry for twenty-four or thirty-six hours. By leaving them to dry for some time they are less liable to get tacky when the final registration is made. The films are placed together in register and held by clips, while a strip of gummed paper is laid over the roughened edge of the films and rubbed into close contact. The back of a knife may be used to rub the paper into the edge of the films. When the gummed paper strip is dry it acts as a hinge, and allows the films to be lifted up, so that a little Canada balsam may be poured between each close up to the paper hinge. A clean cover glass is required. It will be noted that these glasses are usually convex on one side and concave on the other. It is well to place the concave side inward, otherwise when the slide is bound up there will be a certain amount of pressure: then the binder gives, air creeps in, displacing the balsam and spoiling the appearance of the slide. A pool of balsam is poured on the centre of the top film and, when the cover glass is laid on, clips are again applied to force out the excess of balsam. The slide should be warmed to assist in expelling the balsam. It should be placed on one side for an hour or so and the balsam round the edges wiped off to allow more to exude. The slide is then cleaned with spirit and bound round the edges in the usual manner. As it is not practicable to have a mask between the cover glass and the films it must be pasted on the outside.

# PHYSICAL CHARACTERISTICS OF RELIEF ENGRAVINGS, ESPECIALLY RELATING TO HALF-TONES.

The following, third, paper of a series which is at present appearing in the "Inland Printer" (New York) continues the discussion of the properties of half-tones which the author, Mr. N. S. Amstutz, has studied, first in connection with his method of line engraving, but later, as will be seen from this and the preceding articles, from the point of view of chemical etching. Previous articles from the "Inland Printer" were reproduced in our issues of April 27 and June 8.

order that the data which have been gathered may be of use to the process-worker, it has been thought best to show graphic curve diagrams of the relation of the black and white dots of the engravings and the press impressions therefrom, shown in the March issue.

The first of the diagrams, Fig. 7, illustrates the characteristic curves of the engravings, Figs. 1, 2, and 3, at 65, 110, and 150 lines per inch for the black and white dots, at various periods of time in acid.

The dotted lines extending toward the left show the probable position of the curves toward the original size of the enamel dot on copper before the etching was commenced, and the extension

FIG. 7.—Engraving characteristic curves of dot diameters from Table A of Figs. 1, 2 and 3.

on towards the right predicates the time when all the black dots would have been entirely etched away. This point would be found where the dotted lines reach the base of the diagram, as at *a* and *b*. The 150-line engraving would, under flat etching, have reached this point in about three-fourths of an hour and the 110-line plate would have advanced to a similar value in about one hour and twenty minutes.

It is interesting to note the decreasing rate of etching for the finer screens. Probably due to spent acid, on account of the larger area of metal to be removed. In the finer-lined screens this does not take place, as the black dots are much more susceptible of "topping," because of the more rapid side action of the acid.

From the diagram it is easy to approximate the diameter of the black or white dots for etching periods other than those given in Table A of the March issue.

Suppose it was desired to know the probable diameter of the black dot of a 65-line screen at the end of twenty-four minutes, instead of at fifteen or thirty minutes, as given in the table, it is only required to follow the "minute" horizontal line at the top of the diagram to "24" minutes and then downward until the 65-line curve is intersected; from which, by following a parallel horizontal line to the left-hand edge, it will be seen that the diameter is about .0041 inch. Conversely, suppose some one was to

demand the necessary time to leave the plate in the acid to produce a black dot of .004 in. diameter at 110 lines, it is only necessary to pass horizontally from .004 to the intersection of the "110-line" curve, and then vertically to the "minute" line where one finds that seventeen minutes' flat etching will be sufficient to produce a black dot .004 in. in diameter on copper, under a given acid strength, 39 deg. Baumé, known as "new iron," starting from an enamel dot on the copper of .006 in. diameter.

From the foregoing, it will be noted that the graphic curves shown give much more information than a table can possibly convey, because it is not apparent from a table what the intermediate values are, and it so frequently happens that it is these very ones

FIG. 8.—Printing characteristic curves of dot diameters from Figs. 1, 2 and 3.

that are missing from a table and for which one finds the most urgent demand.

If the process-worker knew of the possibilities of the graphic curve, he would familiarise himself with its construction and therefrom, by noting three or four positions or values of any given phenomenon, deduce the law to which it is amenable in a few minutes, without requiring hours of laborious calculations. One can put into tabular form the results of various and sundry measurements, but the bare figures do not convey any hint, except to a mathematical expert, as to the law which underlies the values given. Furthermore, should any value or condition occur somewhere between the values noted, he is entirely at sea as to the relation of the one to the other.

In order that the engraving and printing characteristics can be easily compared, the latter are shown in Fig. 8. In comparing these two diagrams, it is interesting to note the divergence of the printing curves from those representing the characteristics of the engravings. Such a comparison at once shows the effects of the overlays, as well as the spreading action, due to the press-work and ink conditions. If the overlays followed the tonal relation of the engravings, the curves of Fig. 8 would be symmetrically disposed in relation to those of the engraving, Fig. 7, showing a uniform modification.

If this was followed consistently, then the curves of Fig. 8 would be located proportionately higher on the diagram for the black dots and lower for the white ones, as the action of the press-work is to broaden the black dots and narrow the white ones.

Reasoning backward, from a given size of printed black or white dot, knowing the spreading effect of the ink and the rate of side action of the acid, it becomes relatively an easy matter to predict

intensification, clearing, printing on the metal, side action in etching overlays, spreading action of the ink and surface to the paper meet the final requirements of a finished result.

The surface of the paper should be, so to speak, "passive," that no special modification of the tonal values takes place, due to its texture. Coated and highly surfaced paper eliminates this for the better grades of printing, but as the half-tone process is forced

FIG. 9.—10 minutes.

FIG. 10.—20 minutes.

FIG. 11.—40 minutes.

SPECIAL 110-line TEST ENGRAVINGS (FLAT ETCHINGS.)  
Data are given in Table F and Figs. 12 and 13.

cate the size of the "enamel" dots on the copper, and therefrom determine their size in the negative before and after intensifying or before and after clearing the same.

It then simply remains to determine the rate of side action of the intensifying and clearing solutions to know positively what size of dot to project on to the ground glass of the camera to hold the

its way to the front in daily newspaper work, the modifying effect of the surface texture must be recognised and proper allowances made therefore in all of the subsequent steps of the process.

The spreading of the ink in printing, to a degree, neutralises the effects of side action in the acid bath, but its modification takes place at a uniform rate away from the edges of all printing surfaces

FIG. 12.—Special 110-line Engraving.  
Characteristic curves of dot diameters and depths from Table F and Figs. 9, 10 and 11.

best working relation throughout all of the successive steps of the process.

Knowing the kind, or rather size, of printed dot that is best adapted for the specific interpretation at hand, places the process-worker upon fundamental ground so that he can then adjust the screen and size of aperture to produce the size of dot that will, after passing through the modifying influences of development,

FIG. 13.—Special 110-line Engraving.  
Characteristic curves of dot areas and percentages of white and black from Table F and Figs. 9, 10 and 11.

or points, regardless of the size of such surfaces or points. If the spreading action was proportional to the variation in area of the same, then the effect of side action in the acid would be neutralised more consistently and to a larger degree.

These remarks apply to inks that are not of the "double-tone" or highly viscid order. When inks of this kind are used, the smallest white dots of the shadows (white when printed with single-tone

become filled with ink by reason of the viscosity of the ink, the colour particles to bridge over the depression, by drawing the ink away from contiguous surfaces, forming a thickness of ink that is greater than that left on the adjacent portions of the printing surface by the ink rollers.

Because a greater physical thickness of pigment is found in the recessions, these will appear darker than the surrounding areas, thereby produce a double-tone effect which can be utilised to considerable advantage if the press and rollers are exclusively used for double-tone purposes. Paradoxically, the ink applied to the dots or type faces appears a maximum black.

The law of interpretation of the screen, etc., will not be the same when single-tone ink is used. Fundamentally, it cannot be the same, hence special treatment is required.

The whole subject is so closely bound up with the modifying effects of overlays and presswork, which, on the basis that "no effect is stronger than its weakest link," neutralises to a marked extent the care and attention that may be given to the dot-relation of the previous stages of the process. Fig. 8 illustrates the effect of tonal aberration due to this cause. It is contended that changes in effects are produced, which cause the reproduction to be a mere pretence, it is time that the fundamentals are studied in a setting of stakes made that shall for all time remove this taint art from "rule of thumb" domination.

The effects of true overlay interpretation should be the retention of the tonal values, harmonising with the qualities of the subject being reproduced; and yet how little is the underlying law of pressure per unit area understood? When the time does come when the make-ready will be constructed in harmony with the whole printing areas, the field will be emancipated from the shackles of uncertainty that now overshadows it.

It is not too much to expect that wide-awake workers will give impetus to the scientific investigation of this subject in all of its related phases.

The statement is ventured that, given a specific subject having values ranging between maximum white and maximum black, a compensated screen negative and a flat etching, without staging, therefrom, the printed result will show more faithful tonal reproduction than a "staged" engraving, because in staging a variable personal equation is introduced. We have come to look on results that are highly keyed as to the whites as a desideratum, and so they are, providing the middle tones are drawn out of relation and sacrificed on the altar of pure whites. In order to further study the scope of half-tone interpretation, Figs. 9, 10, and 11 have been made so as to show this value under ten-minute, twenty-minute, and forty-minute periods of time in the acid.

These are made up of four 1-in. squares, and are numbered respectively 1, 2, and 3. The squares that carry these numbers are black, the ones directly beneath are the greys, the ones diagonally opposite the shadows and those to the right are the whites.

True tonal interpretation may be represented by a straight line "curve." The basis of comparison is a unit area comprising the square of the pitch, or an area 1-110 in. on each side, which encloses .0091 by .0091, equalling .00008281 square inch.

In the dead-black portions, obviously, the whole area is black; in the pure whites the whole area should be white, but the evidence of a black dot persists. This can be brought to such a minute dimension, however, that the very small per cent. of black, in what would otherwise be pure white, is negligible for practical work. The middle tone value will come when one-half of unit area is black and one-half white. In the three-quarter region, away from the white, 75 per cent. of the area will be black and 25 per cent. white, and going in the opposite direction one finds the reverse, or 75 per cent. of white to 25 per cent. of black. Linking up these points, one finds a straight line connecting all of them.

It is the aim of the half-tone worker to show such an interpretation in the finished print, but the great average of work does not come as close as it might to these ideal conditions, because, as already stated, of the many modifying influences encountered between the subject itself and the final print (not the engraver's proof).

However, if one does not seek for fundamentals and a familiarity with underlying laws, one cannot reason intelligently from causes to effects, so it behoves every worker to strive for greater proficiency in his chosen craft by working to a purpose.

Figs. 9, 10, and 11 show dead blacks, the smallest black dots of the "whites," the smallest white dots of the shadows and an intermediate grey tone. From these one may judge as to the relation that interpretation bears to the printing areas, and how close the theoretical requirements are met. One should not find a coincidence between the engravings themselves and the theoretical "curve," because allowances must be made for the spreading action of the ink and paper conditions in printing.

These engravings further show the rate of acid action in relation to depth of etch, as each one has been measured and the results are shown in the curves of Fig. 12.

Table F summarises the data of Figs. 9, 10, and 11 for 110-line screens. In this table the original characteristics of the dots as produced in "enamel" on the copper are first given for the black dots in the "whites"; the white dots of the greys, and the white dots of the shadows and the succeeding characteristics of similar tone-values at the end of ten-minute, twenty-minute, and forty-minute flat etches.

In order to simplify the numerical values for the areas, they are given in ten-millionth parts of a square inch; thus the area of a black dot under ten minutes etching is given at 49.1, which actually reads .00000491 square inch.

The curves in Fig 12, in addition to the diameter characteristics of the white and black dots of the "whites," greys, and shadows, for various periods of time in the acid, also show the measured depths of the etching action for the same tonal values. In addition

White," or unit area, at 110 lines per inch = .0091 × .0091 = .00008281 square inch. In the table areas the ciphers are omitted, and to conform therewith, unit area becomes 828.

● = smallest black dots in whites.      ○ = white dots in Grays.      ○ = smallest white dots in Shadows.

tion, two dotted curves are shown, which illustrate the estimated depth for various etching periods that were given in Table B of the March issue; these curves relate to the white and black dots only.

Fig. 13 shows the area and percentage curves, the values of which are tabulated in Table F. It is extremely interesting to note the

Fig. 14.—"Hot Circulation."

interrelated changes that take place in the dimensions of the engravings under variable time periods of etching. From these there has been deduced the existence of a second acceleration. This law is applicable to the greys from the moment a series of white dots, A, of quadratic relation (Fig. 15) have reached such an enlargement of border,  $A^1$ , shown at  $b$ , as to break down the wall of metal,  $b^1$ , which, prior thereto, separated and confined the acid action to four disconnected but contiguous depressions, A

Fig. 15.—"Periodic Acceleration."

(white dots). The form of black dot will now approximate the assembling of four crescents, with their convex portions meeting each other.

The horns of the crescents will unite in pairs to form pointed projections,  $a$ , reaching into the space of acid activity, where the acid will attack them from both sides simultaneously, so as to

cause them to recede toward the centre of the unetched area. The concave portions of the crescents will not recede, at  $a^2$ , toward the centre of the dot as rapidly as the horns do, over the distance  $a^1$ , hence the dot area is not reduced uniformly, but at a differential rate, thereby causing a second acceleration, which, if not compensated for by special dot formation through screen distance and diaphragm outline, will nullify the middle tone translation to the great perplexity of the operator.

These horns, as stated, recede faster than the concave portions and in consequence the area is reduced more rapidly per unit time so long as they exist than when the remaining dot has attained a square or circular form.

The other law that is predicated by the investigations so far made is the differential rate of etching around the black dots of the "whites" in contrast to that within the white dots of the shadows. A name is ventured for each phenomenon. The first may be called periodic acceleration, and the last dot circulation. In order to illustrate these, Figs. 14 and 15 are used. In Fig. 14 four black dots, B, are shown; around these arrows are drawn indicating the possible direction of acid activity around the dots when there is little rocking and no brushing in the etching tank. At the points,  $b$ , midway between the dots, arrows are shown pointing in the same direction, indicating a harmony of the white around any one dot to that of two adjacent ones. The interaction predicated is similar to that of two pairs of intermeshed toothed wheels, wherein the rotation of any one imparts rotation at the same velocity to the other three of a given set of four. Ignoring friction, any number of wheels so connected might be set in rotation by moving any one, and the axis of each wheel would represent a black dot of the "whites."

N. S. AMSTUTZ.

## THE CROOKE-IRVING CASE.

### REVERSAL OF JUDGMENT.

ON Friday last, in the First Division of the Court of Sessions, before the Lord President and Lords Kinnear and Pearson, judgment was given in the reclaiming note presented by William Crooke, photographer, 103, Princes Street, Edinburgh, against the interlocutor of Lord Ardwall in the action by Mr. Crooke against the Scots Pictorial Publishing Company (Limited), 180, Hope Street, Glasgow, to interdict them from continuing and repeating the publication in the "Society Pictorial" of a photograph of the late Sir Henry Irving, and to have it declared that the defenders had infringed his copyright by publishing the photograph in the paper on November 12, 1904. There was also a conclusion for £2,000 damages, and for delivery of all copies made, or, failing delivery, payment of £1,000 damages. Lord Ardwall assozied the defenders, with expenses.

The Division recalled the judgment of the Lord Ordinary, and awarded the pursuer £5 damages, but in respect of a tender of £200 by the defenders when the defences were lodged, found the defenders entitled to expenses since the date of the tender.

The Lord President said in this case the defenders, the Scots Pictorial Publishing Company, admittedly published in the "Society Pictorial" a portrait of the late Sir Henry Irving, and they did so admittedly, without the leave asked or obtained of the pursuer, Mr. Crooke. Although at first in these proceedings it was stated that the portrait which they published was not a portrait taken from the original sketch, it was now practically admitted, because there was really no controversy upon the matter, that that was not so, and that that portrait was a reproduction of the photograph of Sir Henry, which was taken by Mr. Crooke, and of the copyright of which Mr. Crooke was the registered owner. The present action accordingly was brought by Mr. Crooke for interdict against them publishing it again and for damages. The defence of the publishing company was that the copyright was not Mr. Crooke's. His Lordship did not think there had really been any controversy upon the general law which was applicable to the question of the copyright of the photographs of sitters who went to photographing establishments to have their portraits done. The law was laid down in the case of *Boucas v. Cooke* and others, in the King's Bench in 1903, and that law had been adopted by the Lord Ordinary in the present case. His Lordship contented himself with quoting the portion of the judgment in

as, which the Lord Ordinary also adopted. It "It seems settled that, if a person goes to a photographer and asks for a sitting, he is entitled to the copyright of the photographs then taken, it being presumed that he is liable to pay for them, and intends to pay for them. On the other hand, it is that if a photographer invites some celebrated person to give him a sitting, and the person agrees to do so, the copyright of the photographs is the photographer's, even though the sitter should afterwards pay for copies. Further, if a third person employs a photographer to take the likeness of another person, whether that person be a celebrated person or not, and arranges for a sitting accordingly, the photographs taken at such a sitting belong to the third person, and he is liable to pay for the sitting." His Lordship entirely adopted the general proposition. The Lord Ordinary had applied that proposition to the present case, and he had assailed the defenders. The Lord Ordinary had written a very long and careful opinion, but round of his judgment might be taken in a single sentence, which—"I hold it proved that the photograph in question was taken by Mr. Shorter; that he is the person entitled to the copyright of it; and that any agreement by him to give up the copyright of the photograph in question was entered into by him under essential duress, induced by the misrepresentations of the pursuer." Accordingly, the Lord Ordinary held the copyright of the photograph to belong to Mr. Shorter, and he assailed the defender. His Lordship had been able to take the same view as the Lord Ordinary. The result of what led up to the matter was not doubtful. It was known that Sir Henry Irving, the distinguished actor, was coming to pay a visit to Edinburgh, and there were at least two, if not more, persons at that time who were very anxious to have Sir Henry's photograph. There was no doubt that Mr. Shorter, who had to do the "Sphere" newspaper, was anxious to publish a photograph of Sir Henry, and he was also undoubtedly anxious to have a photograph, of which he should have the copyright. It was, his Lordship thought, satisfactorily proved that Mr. Shorter, who was a friend of Sir Henry, having been unable to get Sir Henry to sit for his photograph in London, seized upon the opportunity of his being in Edinburgh to have his photograph taken. It was also quite certain that Mr. Crooke wished to have a photograph of Sir Henry, probably for the advertisement of his own powers of photography, and he was using, probably, also as an advertisement, to take the photographs, and to give a copy of the photograph so taken to each of the members of the Pen and Pencil Club, he having, it seemed, done the same thing on other occasions with regard to celebrities. The result of all that was that arrangements were made for Sir Henry to sit for Mr. Crooke. There was some controversy upon the terms which preceded the granting of that sitting, and it was very strongly pressed upon the Court that Mr. Crooke had gone further than the true facts warranted him in a certain letter, in which, in an earlier period, when Mr. Shorter applied to him, he replied to Mr. Shorter that arrangements were already in train for Sir Henry giving him a sitting. His Lordship was bound to say he thought Mr. Crooke's letter did go beyond the very strict statement of facts, but he did not think for the purpose of this case that very much mattered, because he thought the result was that Sir Henry Irving came to Mr. Crooke's studio, well knowing that he was to be photographed for more persons than one. He knew he was going to be photographed for the purpose of a copy of the photograph for his friend Mr. Shorter. Nay, more, if it had not been for his friendship for Mr. Shorter his Lordship thought that it was more than probable that Sir Henry would have given no sitting at all. At the same time he equally well knew that while he was there he was going to be photographed with a view to a presentation copy of the photograph being given to the members of the Pen and Pencil Club, and he knew also he was going to be photographed for Mr. Crooke, so far as copyright was concerned. Sir Henry, through his agent, made a very proper and obvious arrangement that as he was putting himself to the trouble of being photographed like that he should be allowed first of all to have a veto upon what photographs were to be published, and, secondly, that he should be allowed to have copies for his friends at so much per copy. All that was arranged, and accordingly Sir Henry went and subjected himself to the ordeal of the camera. There was a little dubiety as to which of the various photographs that were thus taken was precisely taken

first. His Lordship did not think that matter could be cleared up with perfect certainty. In Mr. Crooke's books the photographs were put in a certain order. That order would make out that the large photograph, which was the subject here of piracy, was taken first. On the other hand, Mr. Crooke himself said that he thought that exceedingly improbable. But his Lordship was bound to say that he did not think that mattered. He did not think that there was an appropriation of photographs made by Sir Henry at the time, saying, "Now, this time I am before the camera the photograph belongs to Mr. Shorter; this time it is for the Pen and Pencil Club, and this time it is for yourself." His Lordship did not think it was commonsense to suppose that anything of that sort happened. Sir Henry, like any other sitter, would be very anxious to get the sitting over as soon as he could. The photographs were taken, and the particular one in question was taken in rather an unusual manner, because at the precise moment at which Sir Henry sat for this large photograph he was operated upon by two cameras at once, the result being the large photograph and the small photograph, which was afterwards given to the Pen and Pencil Club. While what precisely passed in the matter of time in the photographer's studio was uncertain, what happened afterwards was perfectly certain, because they had got the correspondence of the parties written at the time when there was no question of that or any other dispute. On May 10, Mr. Crooke having submitted to Sir Henry, as he promised, the whole of the negatives of the photographs thus taken, wrote to Mr. Shorter:—"Sir,—I am herewith sending you the two negatives of Sir Henry Irving of which you can buy the sole copyright; no copies having been printed except two of each for himself. I am also sending you for inspection a copy of the picture taken for the Pen and Pencil Club. My price for the sole copyright and possession of the two negatives, and also the permission to reproduce, if you wish, the full-length now sent for your inspection, with those Sir Henry is reserving for himself, if he has no objection, is £5 5s." Mr. Shorter, on May 11, wrote to Mr. Crooke as follows:—"Dear Sir,—I accept your terms, and shall be glad if you will send in an account for five guineas to cover the copyright of the two pictures. I am also glad of your permission to reproduce the one sent to the Pen and Pencil Club, which I actually prefer." That, to his Lordship's mind, ended the business. That was an offer by Mr. Crooke for the sum of five guineas to give up the copyright of these two photographs, and it was accepted by Mr. Shorter. His Lordship was bound to say he did not understand what the Lord Ordinary meant by the misrepresentation of the pursuer. There was no representation in the letter at all. His Lordship could not call representation the mere statement of fact that Sir Henry had barred the publication of certain of the negatives altogether. Mr. Crooke's statement was that Sir Henry had chosen two, that the pursuer proposed to keep one for the purposes of the Pen and Pencil Club, and there was the offer of the other two to Mr. Shorter. If Mr. Shorter had wanted to make that a question of selection he was bound in his letter to say so. Mr. Shorter did not kick at the idea of the larger one being reserved for the Pen and Pencil Club. He did not start any theory such as was now started, which was really a theory, of there having been a determinate appropriation at the time Sir Henry sat in front of the camera. If that was so, it seemed to his Lordship to end the case, the result being that as the only person who paid five guineas at all was Mr. Shorter, who, for that sum, purchased these two pictures, none of which was the one in question, the copyright must be in Mr. Crooke, simply because nobody else paid for it. His Lordship was of opinion that the pursuer was entitled to decree. What the decree was to be was another matter. It did not seem to his Lordship a case where there was any necessity for pronouncing interdict, because the matter had been done, and he did not suppose that the paper proposed to reproduce the picture again. Then there was the matter of damages. They had evidence that, supposing a paper had to ask a photographer to allow a picture to be reproduced, the ordinary price would be from half a guinea to one guinea. Now here there was taken what was called "French leave," and no doubt also by the taking of "French leave," the photographer did not get what he generally did get, the right to stipulate that his name as the author of the photograph should be put in a conspicuous position. But then the damage Mr. Crooke had suffered seemed to his Lordship exceedingly small, because one could not, as a person of common-

sense, think, that really that copyright was a matter in which there was a great deal of money. The only persons who would want it would be people who wanted the photographs for themselves, or other newspapers who wanted to reproduce it, and they would probably get it for half a guinea or a guinea. His Lordship thought the pursuer would be amply remunerated here if he got an award of five guineas, which, of course, would carry expense of process.

The other Judges concurred.

Mr. Johnston, K.C., for the defendants, moved for expenses in respect of a tender in process. At the lodging of the defences the defenders put in a minute tendering the pursuer (1) delivery of the whole of the copies of the picture complained of by the pursuer, so far as in the possession of the defenders, or at since the raising of the action; (2) a judicial undertaking not to print or publish any further copies of the picture, or, alternatively, if the pursuer desired, the defenders consented to interdict in terms of the first conclusion of the summons; and (3) the sum of £20, together with taxed expenses to date in full of the conclusions of the summons.

The Lord President said the tender was a proper one in the action, and carried expenses to the defenders since its date.

#### "ETCHOGRAPH PLATES."

A PHOTOGRAPHIC accessory which is new, we believe, to this country, has been put upon the market in America by W. Jay Little, of 363, Boylston Street, Boston, Mass., under the above name. "Etchograph Plates," according to the "American Amateur Photographer," "offer more possibilities in the way of improving negatives than anything we have seen in a long while. It consists of sheets of thin celluloid coated with a transparent and non-actinic soft etching ground, which may easily be etched away with a needle. Its first and most obvious use is the rendition of a photograph into line. The

plate is laid on a print or negative, and all outlines and shadows are traced, using a firm stroke and a sketchy manner. When this is finished we have a transparent drawing on a red ground. This may be added to as desired, and is then printed on any photographic paper, giving the effect of an etching."

"Another variety of the tissue has a stippled effect. By simply printing a hard negative through this on any paper, the print has all the delicate quality of a gum print. When etched the effect is exactly that of a mezzotint engraving. Pure whites, if needed, must be added to the plate by means of a spotting colour, which is furnished."

"Variety No. 3 is very thin, and is intended especially for portrait backgrounds. By photographing a subject against a black background and then etching a line background on variety Nos. 2 or 3, or wiping out a landscape on No. 3 (a very easy proceeding, as it should be only a suggestion), an infinite variety of effects can be obtained

without working on or altering the original negative. This is an advantage not to be despised, as several different backgrounds can be made and used if variety is desired, or if the first one is not wholly successful.

"Another use which the writer has discovered is for local reduction or intensification of negatives. The plate is laid over the negative and scraped over the dense parts, as, for instance, the clouds of an overdeveloped landscape. Very thin parts can be protected by an extra coat of spotting medium if necessary. The change which this process will produce in a strong negative is marvellous."

#### DEATH OF MR. A. H. WALL.

Mr. A. H. Wall, well-known to large numbers of the older generation of photographers, died on Sunday last, June 24, at Stratford-on-Avon.

One of the most beautiful personalities that ever graced photography has been removed by the death of Alfred H. Wall, at his home in Stratford-on-Avon, on Sunday, June 24, at the ripe age of seventy-eight years. Mr. Wall was born in London; his early youth was spoiled by an unsympathetic step-father, and, running away from home, he first joined one of the early Daguerreotypists and soon afterward "went on" as a super in the company of the great Macready, who was attracted by the lad, and soon gave him a small part. His sketches were admired by Findlay, a famous miniaturist of the day, who engaged him to paint the backgrounds of his miniatures, and in 1850 Mr. Wall began business with a partner in Cheapside, London, as miniature painters and Daguerreotypists. The miniature was killed by the Daguerreotype. In 1851 Mr. Wall was assistant to a photographer working near the Great Exhibition, and later opened a studio in the Strand as miniaturist and portrait painter—a complete failure. In 1852 he married and set out with his bride as a touring portrait painter, with fair success. He used the name of R. A. Seymour, and in the "Photographic News" for 1861 will be found the story of his tour. The early death of his wife sent him back to the stage, where he made some success in a touring company, and in more than one provincial stock company, as actor, scene-painter, and play-wright. The three plays he produced were successful. One of them, "The Hermit," is still occasionally produced, and had the distinction, almost, if not quite unique, of being constantly in the repertoires of touring companies for forty years.

In 1864 Mr. Wall was again in London, and in photography, and began the publication of "The Art Student," an excellent little illustrated journal that was before its time. For Hazell, Watson and Viney he edited "The Illustrated Photographer" during 1868, '69 and '70, another magazine that was before its time; and since then his connection with photography has been limited to occasional contributions and criticism. In earlier years he was a regular contributor to THE BRITISH JOURNAL; then, in consequence of a political revolution transferred his pen and influence to "The Photographic News," and for some time, when "The News" was in difficulties, wrote almost the whole of the matter in each issue.

In general journalism he acted for some time as assistant editor of "The Illustrated Sporting and Dramatic News"; he founded and edited for three years the Australian edition of "The Illustrated London News," and on return to England edited several papers and magazines for the same proprietors. For Cassell and Co., Ltd., he wrote many books, chiefly for children; he wrote and illustrated several of their topographical books, and for them wrote his most successful volume, "Fifty Years of a Good Queen's Reign," published in 1887, and re-issued as "Sixty Years" in 1897.

About 1888 Mr. Wall received the very congenial appointment of librarian to the Shakespeare Memorial Library at Stratford-on-Avon, which he held until his retirement from active life in 1895. In his London days he was the intimate friend of Rejlander, Sutton, Baden Pritchard, Jabez Hughes, Woodbury, Traill Taylor, and all the men who were making photographic history. He founded the old South London Photographic Society, and was one of the founders and most active members of the Solar Club.

Even in retirement at Stratford-on-Avon he was always active, often planning, and occasionally executing successfully, new literary schemes. Quite recently he published a school History of King Alfred, through Chapman and Hall. Personally, he was a charming

le, companion, and raconteur, much sought after by literary  
ors to Stratford-on-Avon, who found his knowledge and his  
ate library over at their service. His purse, too, was always  
for a needy friend, with the result that he was never in a wealthy  
tion, though his income was large at times. The death of his  
nd wife a few months ago was a shock from which he never  
ed completely, and his own death, at the end of an illness of  
ral weeks, was the result of age and natural decay. H. S. W.

re regret also to announce the death on Monday last of Mr. J.  
rdia, of the well-known firm of Newman and Guardia, of  
tisbury Avenue, W. Mr. Guardia had been suffering from an  
nal trouble for some time past, and was forced to undergo an  
ation, from which we are sorry to say he did not recover.

## Patent News.

rocess patents—applications and specifications—are treated in  
to Mechanical Notes."

he following applications were made for Patents from June 11 to

FLASH LAMPS.—No. 13,418. Improvements in supports for flash  
lamps. Ferdinand Hrdliczka-Csiszar, Birkbeck Bank Chambers,  
Southampton Buildings, London.

STEREOSCOPES.—No. 13,449. Improved form of stereoscope and  
method of producing views for same. Courtney Spencer Jones,  
Mountsorrel, Woodford Green, Essex.

LIGHT DEVELOPMENT.—No. 13,451. Improvements in apparatus  
for developing and fixing photographs in daylight. Percy Free-  
man Lee, 54, Colne Road, Burnley.

ORTHOCHROMATIC PLATES.—No. 13,561. Improvements in the manu-  
facture of iso or orthochromatic plates. Edwin Ebernezer Burn-  
nett, 2, Heber Road, Cricklewood, London.

PRINTING APPARATUS.—No. 13,738. Improvements in printing  
apparatus for photographs by artificial light. Hermann Muller,  
48, Avenue de la Beauté, Parc St. Maur, France.

PRINTING FRAMES.—No. 13,739. Improvements in printing frames.  
Hermann Muller, 48, Avenue de la Beauté, Parc St. Maur, France.

### COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the  
Patent Office, 25, Southampton Buildings, Chancery Lane,  
London, W.C.

PRINTING.—No. 17,007, 1905. The three claims for this  
invention are as follows:—1. A bath for use in photographic  
printing in pigmented gelatine or other colloid or mucilaginous  
substances, from a metallic silver image produced by develop-  
ment, consisting of (1) Potassium or other alkali bichromate;  
(2) Potassium or other alkali ferricyanide; (3) Potassium or other  
alkali bromide, or one or more of the soluble haloid salts of an  
alkali; (4) Water. 2. The improved method of producing pic-  
tures in insoluble gelatine or other colloid which consists in im-  
pregnating a gelatine or other colloid surface on a suitable  
support with a solution as claimed in (1), to which may be added  
alum and citric acid, placing in contact with the gelatine to other  
colloid surface a metallic silver image produced by development  
in any support separating the two supports, and washing the  
gelatine or other colloid surface, whether adhering to the metallic  
silver image or to its original support, or whether it has been  
transferred to another support. (3). The process of producing  
picture in pigmented gum by mixing a concentrated solution of  
the bath claimed in (1) with a solution of pigmented gum, and  
spreading the same in the metallic silver print produced by  
development. The solution in which the tissue is soaked is  
called the "pigmenting solution" by the patentee, who directs  
its use as follows:—"I soak a piece of paper coated with pig-  
mented gelatine, otherwise called carbon tissue or pigment plaster  
in the pigmenting bath until it becomes saturated. In the  
meantime I place a bromide print or other image consisting of  
metallic silver in a dish of cold water. As soon as the pigment  
plaster in the pigmenting bath has become limp or saturated, I

withdraw it from the bath and place it face upwards upon a  
glass plate. I now take the bromide print or other image, con-  
sisting of metallic silver from the dish of water, and place it  
carefully upon the pigment plaster lying upon the glass plate, and  
squeegee the two papers into contact. I then place the combined  
papers upon blotting paper until ready for development. Up to  
this point the method of producing a pigmented picture upon the  
original silver print, and an impression for transfer upon an-  
other support, is the same. After the squeegeed papers have  
been in contact about 20 or 30 minutes the image of the silver  
print will have acted upon the film of the pigmented gelatine  
and the two papers will require to be separated. There are two  
methods of separating these papers; according to the first method,  
when the original silver print is intended to be the support of the  
picture, the adhering papers are soaked in hot water and  
separated, and the development takes place by washing away from  
the silver print all the pigmented gelatine adhering thereto that  
has not been rendered insoluble by the action of the metallic  
silver. The black silver of the print will have become a faint  
brown in the operation. According to the second method, when  
it is desired to transfer the gelatine impression to another sup-  
port, then the two adhering papers are plunged into cold water  
and separated by slowly and firmly pulling them asunder. In this  
case the pigmented gelatine film remains on its support and  
holds an impression of the silver image, and may be squeegeed  
down upon a fresh support and developed by removing the  
original support, washing away the soluble gelatine and leaving  
the picture on the fresh support. The silver print may then be  
washed and re-developed by any of the usual developers for  
bromide prints, and again washed, when it will serve for the  
production of another pigment print by being treated according  
to the second method above described. In this manner several  
transfer prints can be obtained from one metallic silver print  
produced by development. Of course, a re-developed silver print  
can be treated as described in the first method, and a pigmented  
picture produced upon the original support. Photographic nega-  
tives may be intensified and lantern slides may be coloured by  
adopting the first method hereinbefore described. Another  
application of my invention relates to collotype printing. If a  
collotype plate prepared in the usual way is soaked in the above-  
mentioned pigmenting bath, and a bromide silver print is  
squeegeed into contact with the surface, and allowed to remain  
in contact for about half an hour, on stripping off the bromide  
print, an impression of the bromide print in insoluble gelatine  
will remain on the surface of the collotype plate, which can then  
be washed and treated as usual, to produce a collotype printing  
surface. The impression is reversed as regards right and left,  
and therefore suitable for mechanical printing. Pictures in pig-  
mented gum can be produced by mixing a concentrated solution  
of the above-mentioned bath with a solution of pigmented gum,  
which is spread on the metallic silver print with a brush or  
otherwise. The results obtained by my invention are not due to  
any catalytic action, but can be traced to chemical decomposition,  
thus:—

The H and  $\text{K}_4\text{FeCy}_6$  reduce the bichromate salt producing  
insolubility of the gelatine, and as these two products are strong  
reducers and are not soluble, they can be made to penetrate the  
film to any desired depth, thus securing rich pictures with perfect  
gradation. Thomas Manly, 140, Haverstock Hill, London.

MULTIPLE-EXPOSURE CAMERAS.—No. 20,570, 1905. The apparatus is  
of the class in which the consecutive exposures are effected by  
means of a rotary shutter having an adjustable aperture which  
permits light to pass while the sensitised medium is momentarily  
at rest, and in which the sensitised surface is supported in a  
carrier receiving a horizontal step-by-step movement, at the end  
of which the plate is raised or lowered, and the step-by-step  
movement reversed, so as to produce a second row of impressions  
below or above the first. Similarly at the end of this movement  
the plate is again raised or lowered, and the step-by-step move-  
ment again reversed. In this way the whole sensitised surface is

covered with a number of rows of photographic impressions, in the well-known manner. Means are provided for imparting an intermittent horizontal reciprocating movement to a sensitised surface across an aperture for the entrance of the actinic rays, and also with adjustable means for moving surface transversely to its line of reciprocations so that a variable number of rows of separate pictures may be obtained on the sensitised surface. James William Anderson, 53, Washington Street, Santa Cruz, Cal., U.S.A.

**OPTICAL LANTIRNS.**—No. 15,607, 1905.—The invention consists of an extension tube formed of a special strip; also of a system of connecting the lens (14) to the adjustable frame (12) by means of the hinge joint (13) situated at the upper part of such frame, and so arranged that the lens may be turned over on to the upper part of the extensible tube. John Ambrose Sprason, St. George's-place, St. George's, Birmingham.

**VIEW FINDER.**—No. 11,670. The invention consists of a view finder which automatically records the alteration in the view for work on the plate when the front bearing the lens is raised. A small view finder is attached to some suitable part of the camera or its fittings, preferably the rising front, or any other part of it which rises with the photographic lens itself. An ordinary small view finder (suitable for the purpose) consists of a small short focus lens set perpendicularly in front with a piece of mirror placed at about an angle of 45 degrees behind it, and a piece of ground glass or another lens horizontally on top. Sometimes there are three lenses in all. The rays that pass through the front lens are reflected upwards by means of the mirror, and the image is seen upon or near the top of the finder. The tops of these finders are frequently masked in proportion to the shape of the sensitive surface. According to the invention we may link or connect any fittings to the front lens of the finder, so as to automatically move it up or down in relation to the other part of the finder as required in connection with the rising front of the camera or lens itself. For instance, one end of the lever may be connected at one side of the finder, or both sides, if necessary, to a rigid part of the camera, and this lever may be slotted at the other end, and connected with pin or pins to any part that holds the small lens of the finder. Small pins may then be fixed at any desired position in the finder body, so as to work in the same slot or slots of the lever or levers. This enables one to graduate the improvements of the finder lens (i.e., impart thereto a differential movement) in proportion to the movement of the rising front of the camera, as it may only require one-eighth of an inch movement of the finder lens to show the same amount of alteration in the view finder as one inch movement of the camera lens taking

the picture. In such a case the action would be that the whole of the finder would rise with the rising front, but the front lens of it being arranged to travel proportionately in the finder, the angle of view would be altered, thus the correct view would be seen in the finder, and similar to that upon the sensitive surface. Arthur Lewis Adams, 26, Charing Cross Road, London.

**FOLDING CAMERAS.**—No. 11,585, 1905. The invention consists of several movements and methods of design, including (1) A lens board which is supported independently of the panel to which is attached, which panel is the door of the camera, and brings the lens into the correct operating position when it is opened. (2) The combination with a closing door of legs adapted to fold away at the sides of the door. (3) A bracket on the lens board affording points of attachment for the toggle links that support the board, and for a link by which the lens board is connected with the door. There are several other claims requiring

diagrams for their explanation. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

**FILM CAMERAS.**—No. 2,300, 1906. The claims are for a construction of film camera in which a system of swinging or movable screens determine the length of film for each successive exposure. The numerous figures are necessary to explain the construction of the apparatus. One of the objects of the invention is to provide such cameras with means for uncovering and presenting for exposure, in the middle of that part of the film which lies between the film-rollers and within the focal plane, more or less of the film according to the length or size of the picture required and for effectively screening or cutting off light from those parts of the film which are not required to be exposed. Another object is to arrange for the operation, control and adjustment of the screening devices directly by motion obtained from the travelling film, as it is being wound on to a take-up roller for removing an exposed portion of film from the field of exposure, and simultaneously winding a successive portion thereof into position for the next exposure, and to provide means for automatically indicating to the operator the length of film which is, at any time uncovered for exposure in the middle of the focal plane of the camera. John Roults Brooks, Finsbury Park, Bromsgrove, Birmingham.

The following Complete Specification is open to public inspection before acceptance under the Patents' Act, 1901:—

**COLOUR SCREENS.**—No. 12,793, 1906. Colour screen for multiple colour photography, and provided with spaces for comparison. Brasseur.

## Exhibitions.

### THE NEW ENGLISH ART CLUB.

USED by the demolition of the Dudley Gallery, the "New" have nested in a low-pitched, glass-roofed, angular (in Dering Yard, 67A, New Bond Street), which, by the of taste, has been made to look quite an inviting gallery. Into this chamber is up a winding stair; but they have pretty things to show you when you're there; fewer than in fact. We warn our readers against visiting this show on day; they will find it a veritable hot-house in more than a figurative sense already known to them. Two or three things out as achievements prompted by a singleness of purpose, most of which are two landscapes—"Richmond, Yorkshire," "Chamond, Surrey"—called "Misty Morning on the Thames." are by Prof. Fredk. Brown, who, so far from subverting art, as do the generality of "New Englishers," seems to dote on the earlier masters, and certainly succeeds in securing the air and nobility, as well as the magic of lighting, that we associate with Turner. We could wish that Prof. Brown would do his teaching, and essay no more of those lugubrious figure studies that leave one untouched: his line is landscape, draughts-like. Mr. Wilson Steer is overweighted with the invitation to his portrait for the Uffizi. Who next? We cry "Ichabod!" to the honour. Of the portraits of Mr. A. E. John, it must be said that they have character. That of Sir John Brunner is a likeness; but his ideas of the colour of flesh point to something wrong either with his eyes or with his motives; they would be near the mark if his subjects were from the mortuary-slab. Mr. J. A. R. A., has a slight sketch—a mere half-hour's work—of a tourist dozing under trees. It has all the charm of a sketch, and is the exact parallel of one in paint. The truth of the light in it is quite remarkable. As a whole, this show is instructive and more highly admonitory. In some of the it is impossible to find any vestige of distinction on any that should admit them to a gallery to which folk are not to be admitted.

## New Materials.

ry" Collodio-chloride Paper. Sold by the Rotary Photographic Co., Ltd., 12, New Union Street, Moorfields, London, C.

placing a collodion paper on the market the Rotary Company truly recognise that there is the opportunity for a greater use of description of print by photographers desirous of offering their customers something better rather than cheaper. A collodion properly made and well-mounted, presents an appearance stamps the photographs as one of distinctive quality, the richness of tone, and fine tones obtainable being responsible for this impression. Hence the wisdom of working collodion in neighbourhoods of extra quality can command an additional price. C.C. paper, orders of our pages should know, requires certain precautions in manipulation which may be disregarded in the case of gelatine paper, whereas, on the other hand, it possesses facilities of which gelatine paper cannot claim possession. The Rotary paper we can be no exception in these respects. Its two varieties, however, matt and glossy—exhibit also certain differences between themselves; for instance, the matt requires considerably more over-printing than the glossy, which latter variety also does not lend itself to black tones in the platinum bath with the readiness of the matt. The paper presents no difficulties if the makers' directions be followed, and we were able to prepare a series of prints, the tones of which, particularly those obtained with gold-platinum, recommended the paper very favourably to us. The Rotary Company give the full and other formulæ in both British and metric measures; the former, we suggest, might be made somewhat easier to prepare by giving round numbers in several cases where an odd number which is very little different has been given. Thus we can imagine that

perceptible difference will be made by employing 100 instead of 96 grains of sodium acetate in the gold toning bath. The results, however, on both the matt and glossy papers, are altogether excellent, and it is worth noting that the makers lay special stress upon the purity of the raw paper bearing the emulsion, the purity of paper, as they point out, entering largely into the production of permanent prints. The paper is put up in packets and boxes at the usual prices (thirty-two quarter-plate sheets for one shilling), and is sold in sheets 24½ by 17 inches at 18s. a quire, a form in which the professional may be glad to purchase it.

## New Apparatus, &c.

"New 'Zambex Skeletons' for Daylight Loading." Made by R. and J. Beck, Ltd., 68, Cornhill, London, E.C.

Despite all that the lay press has done, the technicalities of photography, we are afraid, are not yet so grafted on to the language that any person could explain precisely what a Zambex Skeleton is, or wherein the old form of skeleton differs from the later one which Messrs. Beck have sent us for review. The Zambex system provides for the exposure and loading in daylight of cut films, which may be purchased *in situ* in the skeleton, or inserted in the empty skeleton

FIG. 3.

FIG. 4.

by the purchaser. The latter can thus please his fancy as to which make of film he uses, buying the packets as ordinarily placed on the market. Fig. 1 shows the skeleton partly exposed. It consists of a series of black paper sheaths, in each of which a film (F) is placed. These sheaths are enclosed in an envelope with the tags (K) projecting from one end, a metal rim, C, which is attached to the middle part of the envelope, serving to secure the latter to the camera back. To change a film, all that is required is to pull up the foremost of the numbered tags, K, thus drawing the first film from the lower to the upper half of the envelope. The envelope folds double when in the camera, and only need be unfolded to change a film. As fast as the lower end of the envelope is emptied, the upper half is filled, so that the complete thickness of the folded skeleton always remains the same, and a constant pressure is always exerted to press the films up to correct register. Figure 3 shows the attachment of the Zambex Skeleton to the camera, and Figure 4 the skeleton opened out to allow of recharging. The loaded skeletons containing one dozen quarter-plate films are sold at 2s. 9d. per dozen; the used skeletons, as we have already said, serving for the exposure of purchased films. In case of working and reloading and in compactness, the new Zambex is superior to the original pattern. In both the absence of mechanism is a highly commendable feature, and the later issue appears to leave nothing to be desired as regards smoothness of working. Messrs.

Beck have developed the system very thoroughly by preparing a series of Zambex cameras, accompanied by instructions, capable of being followed by those without any previous knowledge of photography.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
30.....	Aberdeen Photographic Assn.	Outing to Culter.
30.....	Bristol Photographic Club	Outing to Pensford.
30.....	Chelsea and District Photo. Soc.	Outing to Strand-on-the-Green.
30.....	Coventry Photo. Club.	Outing to Offchurch.
30.....	Hull Photographic Society	Outing to Little Wighinton.
July.		
2.....	South London Photo. Society..	"Copying." F. W. Brookman.
2.....	Southampton Camera Club	"Floral Photography." A. E. Henley.
3.....	Hackney Photographic Society	Question Box.
3.....	Manchester Amat. Photo. Soc.	Page Croft Gum Process Demonstration
3.....	Sheffield Photographic Society	and Exhibition. S. L. Coulthurst.
4.....	Bristol Photographic Club	Annual Meeting.
4.....	Leeds Camera Club	Technical Night at Headquarters.
5.....	Hull Photographic Society	"Films & Plates."
		General Meeting.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held June 26, the President, Major-General Waterhouse, in the chair. The Chairman announced that sanction had been obtained for the removal of the partition wall between the meeting and council rooms, and that this alteration in the premises would give the Society a large meeting room, and avoid the overcrowding which had been unavoidable at many meetings. The work would be done during the summer recess.

Mr. C. Welborne Piper then demonstrated the stop-clock designed by him and recently reviewed in our columns on its being placed on the market by Messrs. W. Butcher and Sons.

A paper on "Comparison of Orthochromatic Plates," by A. J. Newton and A. J. Bull was then read by Mr. Newton. The authors gave the results of spectrum tests of commercial plates, classifying these latter as green-sensitive and panchromatic, and giving also results with collodion emulsion and bathed plates. They had tried two commercial samples of alizarine blue without success for red sensitising, but with a sample supplied by Mr. Scooble they had obtained some red-sensitiveness, but with very low speed.

Mr. Newton then read a paper by Mr. Bull and himself on "The Absorption of Ultra-Violet Rays by the Glass and Apparatus used by Photographers," in which they showed that the major portion of the action on a wet plate was due to the ultra-violet rays, and hence the advantage of enclosed arc lamps for wet collodion work. They also showed the advantage of cutting out the ultra-violet when photographing originals bearing pigments which differed greatly in their absorptive or reflective properties towards these rays. The various "process" whites were instanced in this respect.

Mr. J. I. Pigg then exhibited some lantern slides, which he described as examples of three-colour work with 1-12 to 1-20 sec. exposure.

Mr. W. L. F. Wastell then read a short paper on the "Talbot" P.O.P., a brand of printing-out paper which he highly commended for the range of tones obtainable with it, and for its general good quality.

**BOURNEMOUTH Y.M.C.A. PHOTOGRAPHIC CLUB.**—The only photographic society in Bournemouth holds its first outing to Christchurch and Mudeford on Wednesday, July 4, under the leadership of the Rev. H. Gibbons. Ladies and gentlemen interested are invited to join. Arrangements have been made to conduct the party by car and motor-boat at an inclusive cost of 2s. 6d. The hon. secretary, Mr. A. D. Johnston, Cairns Memorial House, will be pleased to furnish any further information, and will be glad to receive the names of intending members of the club, the subscription to non-members of the Y.M.C.A. being 4s. per annum.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—For some years past the

South London Photographic Society have held an annual competition in honour of their first president, F. W. Edwards. A medal is offered for the best monochrome rendering of a colour original, and at a recent meeting Mr. E. J. Wall came down and gave a lecture on "How to Win the Edwards Memorial Competition." After explaining the relationship of colour, the lecturer said an ortho plate sensitive to red and a suitable screen were required, but there was no necessity for an expensive filter. Though he preferred making his own screens, members could find all they needed from the now well-known commercial filter which should be placed in the dark slide with the plate. The increased times of exposure could be quickly found by experiment and might vary from five to ten times the normal, according to the plate chosen. As the plates were practically sensitive to light, they should be handled in darkness. Looking at the plate did no good, and in his own practice he never saw the plate until it came out of the fixing bath. He used either an M.Q. developer which he knew required five minutes to develop the plate, or ordinary adurol developer, which took six minutes. He considered pictures should be copied out of doors, and, as a final tip, advised all competitors to expose a slip of bromide paper in steps of 1, 4, 8, 16, 32, and 64 seconds, develop to form a scale of tones from white to black, and fix to frame of picture when copying. If the resulting negative produced a bromide print in which all the tones of the black and white scale were correctly produced, then the colour tones would also be correct, and the print would be the best the negative would give.

**WEST SURREY PHOTOGRAPHIC SOCIETY.**—On June 20 a lecture "Street Photography," by Mr. A. Lockett, was read. A standard camera was stated to be of little use for this class of work, owing to the notice it invariably attracted and its inconvenience when opportunities have to be seized on the spur of the moment. Holding the camera at a low level was recommended as giving the most picturesque results, and it was noted as a merit of the reflex type of apparatus that it practically compelled the operator to do this. The advantages of an anastigmat lens of large aperture, in conjunction with a focal-plane shutter, were recognised, if many figures or vehicles in rapid motion were to be taken; but for purely pictorial work, in which too many figures or vehicles would be a demerit rather than otherwise, it was said that a rapid rectilinear at f/8 or f/11, and an ordinary diaphragm or bellows lens shutter would give quite satisfactory negatives with extra-rapid plates, except on very dull days.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Meeting June 21, Mr. Teape in the chair. Mr. A. L. Henderson showed a stereoscope in the form of a book, which was patented in 1856 by Langenheim, and again with improvements in 1856 by V. Lloyd. Either prints or transparencies might be viewed by its aid, and it also acted as a storage box for prints, of which 24 or 36 might be inserted or a less number of transparencies. It was covered in morocco, and titled "Stereoscopic History." It was generally thought that this might be improved and put on the market again with profit to the producer. The following were nominated as officers for the coming financial year, the election taking place at the annual general meeting on Thursday, the 28th. Trustees—T. E. Freshwater and A. Haddon. Committee—Beckett, D. W. Hart, Ernest Human, J. S. Teape, A. E. Smith, J. T. French, A. B. E. Fry, S. C. Mote, Furley Lewis, T. K. Grant, R. J. Kindon, J. E. Ellam, and W. R. Stretton. Hon. recorder—Ernest Human. Lanternist—E. T. Wright. Librarian—W. J. Ferry. Hon. secretary and treasurer—Herbert C. Rapson. Delegates to the R.P.S.—J. S. Teape, Ernest Human, Furley Lewis and H. C. Rapson. Auditors—A. B. E. Fry and W. R. Stretton.

**SOUTHEAST PHOTOGRAPHIC SOCIETY.**—On June 25 there was opened a free exhibition of members' work. Mr. F. J. Mortimer, F.R.P.S. acted as sole judge of 150 entries. The president's silver challenge shield, for the best four pictures that had not previously obtained an award, was won by Mr. L. J. Steele for prints titled respectively "The Incense Bearer," "By the Fireside," "The Garden of Allah," and "Sons of the Desert." Silver medals were also awarded to Mr. S. Dawe for a figure study, to Mr. M. W. Cliffe for a picture of street architecture, and to Mr. F. Cooley-Martin for a landscape by a member who had not previously won any award.

## CATALOGUES AND TRADE NOTICES.

Messrs. Raines and Co. know as much about making and finishing regiments as they do about producing a handsome price list, their printers have cause for mutual congratulations, and as catalogue making is quite incidental to the large Ealing business, and has to be done only once a year, there is good reason to suppose that Messrs. Raines know a good deal less about that than about their business proper. To those who have proved the high standard of the firm's commercial work for the trade, all this no doubt sounds like pure nonsense, but we may, nevertheless, draw the attention of those who without such experience to the fact that the taste and judgment exercised in the supervision of such a list as Messrs. Raines' necessarily means the possession of abilities which are of the greatest importance to a successful enlarging business. The list shows that Messrs. Raines are original, and can appreciate good quality—namely, they are in love with any article which is as good as it can be made. There are one or two new specialties in the list, the prices are set in some instances, and are based throughout on the supply of good creditable work at a reasonable figure. The list is one which professional photographers may obtain free, and they should certainly apply for it.

The firm of Fallowfield, 146, Charing Cross Road, has issued a very useful condensed list of prices of dry plates and papers in all the British and Continental. It is the most complete and handy compilation obtainable, and is sent free.

Messrs. Houghtons, Ltd., have issued a supplement to their 1906 price list, an act of supererogation on their part we were at first inclined to think, but we perceive that the supplement contains revised prices and descriptions of many new articles. In appearance and size (16 pages) it is a testimony to the magnitude of Messrs. Houghtons' operations. The supplement is sent to bona fide dealers. Amateur purchasers may obtain a list of selected apparatus post free on application.

Mr. J. R. CAVE, 52, Nevill Street, Southport, sends us his catalogue of photographic requisites, the size (150 pages) and style of which should gratify residents in Southport from the evidence afforded by the large and representative way in which Mr. Cave holds stock of photographic materials and apparatus.

## News and Notes.

**BRISTOL Photographic Club.**—This Club is energetically pushing on the arrangements for its exhibition next October, and are successfully interesting prominent citizens of Bristol. The patron already includes many notabilities, including the Bishop and odd M.P. or two. The judges will be Messrs. Reginald Craigie, H. Evans, and F. M. Sutcliffe. The hon. exhibition secretary Mr. J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.

The international celebration of the Coal Tar Colour Jubilee, which takes the form of a memorial to Dr. W. H. Perkins, to whom the discovery of the aniline dyes is due, takes place on July 26 and 27, when the following programme will be carried out:—July 26.—11 a.m.: Meeting at the Royal Institution for the presentation to Dr. Perkin of portrait, bust, addresses, etc.; ladies are invited. 7 p.m.: Banquet at the Whitehall Rooms, Hotel Metropole; many distinguished guests are expected to be present. July 27.—2-6 p.m.: Visit to the original works at Greenford where mauve was first manufactured, and garden party at Dr. Perkin's house. Train from Paddington (G.W.R.) at 2.15 p.m. Greenford. Return from Sudbury by G.C.R. at 6 p.m.; ladies are invited. 8.30 p.m.: Soirée at the Leathersellers' Hall, at the invitation of Dr. and Mrs. Perkin; ladies are invited.

The Leeds Photographic Society is opening an exhibition of photographs of Herr R. Dührkoop, as shown at the BRITISH JOURNAL OF PHOTOGRAPHY at the Philosophical Hall, Park Row, Leeds, until July 7. The exhibition, it is hoped, will draw the attention of photo-

graphers in Leeds to the Society, which, though the oldest in the Kingdom, is renewing its youth in a variety of ways.

MR. ARTHUR WHITING, a contributor to the B.J. on retouching matters, and author of Messrs. Dawbarn and Ward's "Retouching," has added a photographic department to his business at 2, Station Road, Bishop's Stortford.

A FIRE broke out last week at 45, Grand Parade, Brighton, premises occupied by Mr. Gascon, photographer. The fire had not obtained a serious hold, and it was quickly extinguished.

MR. GEORGE EASTMAN, of Rochester, N.Y., so we learn from "Science," has subscribed £200 annually for the next three years to enable the continuance of research work in photography at the Yerkes Observatory of the University of Chicago. The investigations will be carried on by Mr. R. James Wallace, photophysicist at the observatory. Mr. Wallace's recent papers on diffraction gratings have appeared in our pages.

DR. W. J. RUSSELL, F.R.S., was down for reading a paper yesterday evening at the Royal Society on "The Action of Plants in a Photographic Plate in the Dark."

**FLUID LENSES.**—Mr. W. A. Rublee, United States Consul-General at Vienna, reports to the Washington Bureau of Manufacturers that a Hungarian chemist has invented a process for producing large and cheap lenses that may be of great value for scientific purposes. It consists essentially in enclosing a fluid substance between hard glass surfaces, similar to watch crystals, in such sort that the glass surfaces correspond with the enclosed liquid as to yield pure transmission of light. Air is, of course, excluded, and evaporation prevented, and it is asserted that the fluid will not suffer by lapse of time or changes of temperature. For astronomical purposes the chief recommendation is that the new lenses, according to this report, can be manufactured of large size and at relatively small cost—a fraction only of what has hitherto been paid for the best telescopic lenses. Experience alone can determine how far these claims are valid.

**PHOTOGRAPHY** is represented this month in the "Magazine of Fine Arts" by a reproduction of Mr. J. C. S. Mummery's "Near Amberley," which is accompanied by some notes on the gum prints of Mr. Mummery, and others by F. C. Tilney. There is also a lengthy appreciation, with a number of reproductions of the exhibition of German artists, at the Grafton Galleries.

MESSRS. GOLD, SMITH, AND CO., Manchester, had their annual picnic on Saturday last to Miller's Dale and Tideswell. The train and catering arrangements were carried out by Messrs. Cook and Son, and the picnic proved most enjoyable. A short toast-list was gone through, and in wishing success to the firm the great business increase during the year was mentioned, as also the continued good feeling between employers and employed. The picnic was a largest on record, and everyone present on the previous occasion a year ago was still in evidence. In response to the toast of the firm, Messrs. Waightuch and Bradshaw suitably replied.

## Commercial & Legal Intelligence.

**EMBEZZLEMENT** by a Canvasser.—William Lacey, photographer, St. John's Wood Road, London, was charged on a warrant, at the Oxford Police Court, last week, for embezzling several sums of money received by him for his employers, Messrs. Gibson and Co. Frank Collins, of North Shields, said prisoner had been employed by the company as a canvasser and collector. He had been instructed to give the moneys he received to witness the same night. Witness had not received certain sums due to Messrs. Gibson and Co. Prisoner's wages were 27s. 6d. per week and railway fares. He was recommended by a woman in London on his engagement. Prisoner pleaded guilty. He said he had had a lot of trouble, and did not take the money with the intention of robbing his employers. He would gladly pay them back. He had a little boy in London who was ill, and he took the money to enable him to go up and

see the boy. Mr. Colcutt said the prosecution did not wish to unduly press the charge. The Mayor said the Bench had considered the circumstances of the case. A fine of 38s., including costs, would be inflicted, or one month's hard labour.

**THE Black Art.**—At the Newtown County Court last week Christopher Jones, sweep and photographer, claimed the balance of an amount due for the supply of photographs of school children from James Shelton, schoolmaster, Llanwnnog. An order for payment was made.

**CARDIFF Bankruptcy.**—Heavy rentals and rates, and competition in business, were the chief causes assigned for the failure of Adolph Joseph Siedle, photographer, Queen Street, Cardiff. The first meeting of his creditors was held at the Cardiff Official Receiver's Office on Saturday, and the statement of affairs showed the gross liabilities were £340 11s. 11d., of which £302 8s. 1d. was expected to rank for dividend, and assets £15 6s. 2d., leaving a deficiency of £287 1s. 11d. Debtor stated that he commenced business in partnership with his brother at Swansea in 1888, and in 1894 they opened a branch at Newport. In 1900 debtor opened a branch business at Cardiff, and five years later he was obliged to close the Newport business in order to reduce his expenses. There were no creditors at the meeting, and the Official Receiver remains the trustee.

**THEFT by a Canvasser.**—A young man named Singleton was charged at the Nottingham Summons Court on June 22 with embezzling two sums of 5s. each, the property of the Brunswick Fine Art Company, Chancery Chambers, St. Peter's Church Walk. The defendant had been in the employ of the prosecuting company for three or four months, his duties being to collect accounts from people who bought enlargements of photographs. A number of sums for which he had given receipts had not been accounted for to his employers. The prosecutors did not wish to press the case, but had brought it as a warning to their many other collectors. Lily Rosenberg, cashier to the company, deposed that the receipts produced were in the defendant's handwriting, but he had not handed over the money to her. Mr. Smith pleaded the defendant's previous good character. He had offered to make up the deficiencies, but the money had been refused. Mr. A. E. Wells, local manager of Messrs. W. H. Smith and Sons' wholesale department, in whose employ Singleton had been for sixteen months, bore testimony to his good character. The defendant was bound over under the First Offenders' Act to come up for judgment if called upon.

**ENLARGEMENT FRAUDS.**—At the Quarter Sessions, Boston, on Monday last, William Nicholls was charged with obtaining various sums of money from different persons at Gosberton, Donington, and elsewhere in the district by offering to make enlargements of photographs. The Chairman, in delivering sentence of the Court, said there had been a bad record against the prisoner for a long time. He mentioned five previous convictions against him for fraud in different parts of the country, and said he was evidently one of a regular "long firm" of fraudulent men, and had been systematically defrauding the public. He was sentenced to twelve months' imprisonment with hard labour.

The increase in the number of these enlargement frauds greatly discourage the employment of any such business methods by photographers who value their reputation. Scarcely a week passes without either the enlargement system or the coupon business turning up in the police courts. We ourselves, by publishing these reports, endeavoured to discourage this branch of the profession.

#### NEW COMPANIES.

**DERBY AND DISTRICT PHOTOGRAPHIC AND GENERAL SUPPLY COMPANY, LIMITED.**—Registered June 19. Capital £3,000, in £1 shares. Objects: to acquire the business carried on by H. J. Blount at 63, London Road, Derby, as the Derby and District Photographic Company, and to carry on the business of photographers, picture-frame dealers, etc. No initial public issue. The first directors (to number not less than three nor more than seven) are: H. J. Blount (chairman), A. H. W. Harrison, S. Gilbert, T. W. Fletcher, and J. Peach. Qualification, 25 shares. Remuneration (except managing director) as fixed by the company. Registered office, 63, London Road, Derby.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE P.P.A. AND ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—I notice that the P.P.A. are trying to introduce general assistants' certificate. I presume that the others will follow. I predict the same for this. Why? Because the P.P.A. has not done what was expected of it. I understood, when it commenced, that it was intended for professionals, not amateur professionals. Yet the Association does not enquire into the mode of business of the so-called professional when he wants to join. The result is that every sticky-back man in the country can have an M.P.P.A. after his name by paying a few shillings a year. There are a great number of men who commenced as amateurs who cannot take a photograph right through. The usual range of such men's abilities is to take a negative, print in silver, and tone it. Retouching they know nothing of; the artistic side they ignore. Their chief aim in life is to get a strong, clear negative. They usually work at full time on their work in a small house with a movable studio put up in the yard. The men who cut prices and buy the cheapest materials and apparatus they can buy.

These men are practically ruining the middle-class trade. There are many men who have paid heavy premiums to learn the profession, who take a pride in their work, who are losing their customers by such men. Yet these amateur-professionals can become recognised as bona-fide professionals by the P.P.A. The assistants see behind the scenes—they know what these men are—the work they do. Is it likely they think much of certificates given out by an association which recognises such workers?

If the P.P.A. would issue certificates for professional photographers, and make the gaining of them depend upon an examination there would be better results perhaps.

The first thing for the P.P.A. to do is to enquire into the professional standing of some of its members, and turn off the undesirable. I do not deny that the gentlemen on the committee are first-class workers, but I do deny that the members represent the true professional.

I think what is required is a Photographic Assistants' Trade Union. As a body they are about the poorest paid men in the country, and have about the longest hours; 10½ and 11 hours are very common among these amateur-professionals for assistants; while the usual salary they pay is 25s. per week, which works out about 4½d. per hour.

A bricklayer's labourer gets 6½d.

Let the P.P.A. get down to the foundation of things and they may do good.—Yours,

DISGUSTED ASSISTANT.

[Our correspondent had better consult the list of members of the P.P.A. to see if he can discover a majority of "backyard studio" photographers.—Eds., B.J.P.]

### URANIUM TONED IMAGES.

To the Editors.

Gentlemen,—I regret that pressure of work prevented me from replying last week to Mr. Welborne Piper's courteous letter of the 15th inst.

I am not quite clear as to whether he suggests that a slide should be cut in half and one part treated with the red-tone bath and the other in the brown-tone bath. If this was his idea, it was also mine in suggesting the use of H. and D. strips. If Mr. Welborne Piper cares to carry out some experiments on these lines I can now let him have two or three quarter-plates exposed in an H. and D. machine, which he can develop and cut, and treat as he likes.

With regard to his method of working with equal quantities of

and ferricyanide in such extremely dilute solutions, one must see what would happen. Taking Clerc's figures as correct, substituting uranium nitrate for the acetate, we should require 9,072 parts respectively to form the red and brown com-

Therefore there would not be enough uranium to form the uranium ferrocyanide, but we should have a small quantity of red salt formed with an excess of 0.25 parts of potassium cyanide in 3,000 parts of solvent. This small excess of ferricyanide would not attack to any extent the metallic silver, therefore we should have the red uranium compound precipitated on a black and the result would be brown, because red on black gives us brown.

This exactly coincides with your correspondent's views. As regards his second method wherein he used a much stronger solution: if this was in the same proportions I should argue that he had the same deposit of the red compound with the formation of some ferrocyanide of silver, the former of which would be dissolved, whilst the ferrocyanide of silver might be converted into orange ferricyanide, and with the subsequent slow toning we get practically the same thing, namely, a red deposit on a black image.

Probably I may point out that a sulphocyanide acidulated gradually with hydrocyanic acid. If your correspondent will also use some acetate in his solution he will probably find that he will get the difficulty of keeping his solution. I have no doubt, too, that potassium citrate would act as well.

Probably the term "fading" has been loosely applied, but still I think it is correct even when used in reference to the uniform change of your correspondent's prints, as the academic definition of fading is to grow pale or dull in tint or colour."

I cannot speak as to the prints varnished by the late Mr. Dresser, but certainly can as to one of his prints of "Aylesford Bridge," which was in my possession for some years. This was a rich red print and gradually acquired a metallic sheen towards the edges, darker, and in patches became a clear yellow, and was finally blown into the dust-bin. One or two of his prints were years back in the possession of the R.P.S., and these were all in tone, and if still in existence they might be worth examination; they must be from twelve to fourteen years old.

As regards slide D, this, with the others, was merely toned to disprove the facts in dispute, and they are of no value to me. Yours faithfully,

E. J. WALL.

#### "STIPPLETTE."

To the Editors.

Gentlemen,—Whilst thanking you sincerely for your more than ample notice in last week's issue of my new method of working black and white and colours, I must point out that owing to a printer's error in the first line of the paragraph, your readers may be led to form an entirely incorrect opinion as to the method and its application. The word "stripping" as printed, suggests some special process to the surface; whereas "stippling," the words which should have been employed, at once convey the correct meaning without ambiguity. There is no "stripping" in "Stipplette," but only the artistic imitation or effect of sable brush stippling and shading—from the boldest to the finest—so exact, although quickly done, that experts cannot detect the difference.—I am, Gentlemen, faithfully,

T. S. BRUCE.

I regret the literal error in describing Mr. Bruce's ingenious process. The context, we hope, did not permit of an erroneous impression being retained of the character of the effects produced by it. Mr. Bruce is leaving a specimen of the process with us, and it may be of interest to anyone interested.—Eds., B.J.P.]

ORTHCOMING function deserving of support is the concert in the Town Hall on July 11 in aid of the building fund of the Union Club. Miss Janotha, Court Pianist to the Emperor of Germany, will be assisted by the band of the Royal Engineers.

The Whitstable Photographic Society meets the first Monday in each month, when a day is fixed for a monthly outing. Those in the neighbourhood should communicate with the Hon. Sec., S. J. Wilson, 38, Canterbury Road, Whitstable.

## Answers to Correspondents.

\*<sup>a</sup> All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\*<sup>b</sup> Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*<sup>c</sup> Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

\*<sup>d</sup> For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

E. H. Neale, 168, High Street, Lincoln. *Photograph of Afternoon Performance of the Triennial Festival, taken in Lincoln Cathedral. Three Photographs of Dr. King, Bishop of Lincoln.*

W. Jennings, 21, Larkhill, Blackburn. *Four Photographs of the Very Rev. Dean Woods, Rector of St. Anne's R.C. Church, Blackburn.*

H. B. Cooper, 13, Abbey Park Road, Leicester. *Photograph of a Street View at Greetham. Photograph of Cottesmore Hall, Cottesmore, Rutlandshire.*

MAGNESIUM.—Would you kindly say what the exposure would be for a statue in a dark building, using magnesium ribbon as the illuminant, and a plate speed 200 H.D., stop  $f/32$ ? If you could say about how many inches of the ribbons should be burnt for the exposure I should be greatly obliged.—B. A.

We are afraid any data will be of little use, but we should advise you to try 200 to 250 grains of the ribbon:  $f/32$  is a small stop for such work; better use  $f/16$  and one-fourth the magnesium.

MR. STEVENS' PHOTOGRAPHS.—In some remarks of yours on Mr. Stevens' flower photographs, you say "the secret is . . . ample exposure and restraint practised in development." What is meant by the latter remark? Restraint by bromide or weak developer, or what? Kindly say.—CATHAY.

We believe Mr. Stevens uses as pyro soda developer without additional bromide and conducts development tentatively by gradual addition of both alkali and pyro, aiming at detail in the shadows without excessive density in the high-lights. Development may last twenty minutes or half an hour.

ELECTRIC LIGHT.—We have an electric light apparatus fixed in our studio, and we are very anxious to get it into working order before we have the dark evenings on us again. The light is one which we think is in general use in studios, the light being reflected into a large white umbrella, and is then reflected very softly on the sitter. It is between four and five thousand candle power. We enclose a small rough print from one of the negatives, and you will see by it that it is far from successful, as it is quite similar to one that has been taken by flashlight. Do you think any improvement would be made if a head screen were used between light and sitter? Any hints that you can kindly give us, so as to improve our work, we shall be very grateful to you for.—ELECTRIC LIGHT.

The light is evidently too small, or else is too far away from the sitter, which amounts to much the same thing. Though your negative may show detail in the shadows it is under-exposed, the tones not bearing a proper relation to each other. If you use a very translucent diffusing screen between the light and the sitter, you will soften the contrast by lowering the tone of the high lights, and this will not affect the exposure. But by the judicious use of a large reflecting screen you can better illuminate the shadow and so shorten the exposures. In some cases both diffuser and reflecting screen may need to be used.

FOREIGN COPYRIGHTS.—May I trouble you to answer in your next where can I get to know if certain foreign photographs are copyright in this country or otherwise, and what would be the cost?—W. FROST WILSON.

If the photographs are copyrighted in a country of origin which subscribes to the Berne Convention, they are, *ipso facto*, copyright in this country. You will find a full explanation

tion of foreign copyright in the current "Almanac." There is usually no easy way of finding if the photographs have been registered abroad, and in some countries registration is not required.

- A. **BOOK ON WORKING-UP.**—Would you kindly say if there is a book published treating on the finishing of enlargements, that is, working up with the brush? Preferably a book with illustrations showing process of hatching, etc. If so, please say publishers and price of same.—**ENTERKIN.**

"Retouching Negatives and Finishing and Colouring Photographs." By Robert Johnson. Published by Marion and Co. Price 2s.

- W. **A. RENNIE.**—Better sensitise the film with bichromate, print out, develop, and dye (in one bath only), as in the Sanger Shepherd colour process. (See article on another page.)

- W. **B.**—She has no power whatever to restrain you from issuing the photographs.

**TONED BROMIDES.**—I notice in your "Journal" a report on some enlargements shown you by Messrs. Jeffery, Edwards and McLeod. You say that sepia-toned enlargements are supplied in two standard shades of colour. As an amateur making enlargements for exhibition, I should be glad if you could inform me how two shades are obtained. I have always understood that the colour obtained is not a standard one, and varies according to the negative. Any formulae you know will be of interest to me, as I am anxious to experiment in the direction of getting two definite colours.—"**TONED BROMIDE.**"

We are not able to say what formulae are used in supplying the enlargements.

- DEVELOPMENT FACTOR.**—In "B.J." of March 9, 1906, Mr. W. B. Ferguson mentioned a paper on "Constant Development Factor." I should be grateful if you would tell me if it is yet published, and where it can be obtained.—**Q. S.**

The paper was read on April 20, and is briefly reported in our issue of April 13. It is published in the May issue of "The Photographic Journal."

**COATING CELLULOID WITH GELATINE.**—(1) Is there any difficulty in coating celluloid with a solution of plain gelatine, say in sheets 12 x 10 in.? I want to use it for some experimental work in carbon. (2) What sort of celluloid is most suitable? Polished both sides or matt on side to be coated? (3) Is any substratum necessary to cause the gelatine to adhere to the celluloid? (4) I suppose the ordinary formula for carbon tissue (minus the pigment) will be suitable for coating. (5) I should also like to coat some of the sheets for stripping. I presume some form of India-rubber solution is necessary as a substratum. Kindly give particulars.—**KAYBOUGH.**

(1) No; if you fix the celluloid flat on a piece of glass, which should be levelled on a levelling stand. It is easy to fix the celluloid temporarily by squeezegeeing down to the glass if the latter is flooded with plain water or a very weak solution of gelatine. (2) If the gelatine is to be subsequently stripped, polished celluloid must be used; if not, we should advise using celluloid matter on one side and coat the matt side. (3) There is no difficulty in making gelatine adhere to matt celluloid. In the case of polished celluloid it is not, however, so easy. It is advisable to quickly polish the surface with a solution of 1 oz. of ether and 19 ozs. of methylated spirit; this gives a very faint bite to the surface to which gelatine will adhere well. (4) This will entirely depend upon what you require the film for. (5) There is not the slightest necessity to use rubber solution; if you simply polish the surface well with French chalk the film will strip very readily even after sensitising, exposing and developing, but it can be made more sure by treating the celluloid with the usual waxing solution as in double transfer, only in this case there is a chance of the film stripping whilst drying.

- AMIDOL STAINS.**—Would you please tell me the best thing to get amidol stains off finger-nails? Been on some time now.—**CHAS. AMES.**

Try ammonium persulphate, rubbed on wet.

- A. **B. C.**—We should say you can afford to wait at least five years. The new departure is at present on its trial. It has yet to be seen if it can be made to pay.

**ARTIFICIAL LIGHT, ETC.**—1. Can you advise me as to a book on ortho-work, especially with regard to portraiture, etc., by focal light—one giving facts and formulae? 2. I fancy I saw an article in the B.J. or other photographic paper some time ago on taking portraits, etc., by lamp or gas light (not mains), but cannot trace it?—**D. B.**

1. We can only refer you to "Practical Orthochrom Photography," by Arthur Payne (Hilffe, ls.). We have an article on the subject appearing shortly. 2. We cannot say. 3. Probably Mawson and Swan, Mosley Street, Newcastle. Tyne, will supply it.

**COMBINED BATH.**—Will you give me a good formula for a combined bath suitable for postcards?—**BATH.**

Two excellent formulae are given in the "Almanac," 1906, p. 974. The following is also satisfactory:—

Ammonium sulphocyanide .....	30 grs.
Salt .....	60 grs.
Lead acetate .....	10 grs.
Hypo .....	4 ozs.
Water to .....	19 ozs.

Dissolve and add with constant stirring:—

Gold chloride .....	2 grs.
Water .....	1 oz.

Allow 1 oz. of this to every postcard.

**PUZZLED.**—You give no data as to the treatment the card has undergone, but we should say that you have been using a combined bath, and that the yellowness is due to sulphur toning. It can also be caused by the cards carrying acid into the fixing bath.

**GLAZING CARDS.**—Can you explain why the accompanying postcard will not strip in glazing? After the hypo bath, they were immersed in alum, and we have tried both plate glass, ferrotype, and they leave the latter better than the glass, which is cleaned with methylated spirit and then rubbed with French chalk. Can you suggest anything better?—**C. BURNHAM.**

We should say that the glass had been touched by fingers after cleaning. A very good method is to immerse the cards in a 5 per cent. solution of formaline after well washing then into methylated spirit. Clean the glass with a mixture of

White tripoli .....	1 ounce.
Liquid ammonia .....	1 ounce.
Methylated spirit .....	19 ounces.

Rub this over the glass, allow to dry on, and then polish with a wash-leather. Take the cards from the spirit, and at once without draining, squeeze down. Another good plan of cleaning the glass is to use the following:—

Castile soap shaved fine .....	2 ounces.
Oil of rosemary .....	1 drachm.
Water .....	2½ ounces.
Methylated spirit .....	17½ ounces.

Pour a little of this on the glass, rub all over it, and then polish. Also one ounce of ordinary resin ointment, to be obtained from any chemist, can be dissolved in a quarter of a pint of turpentine, and a little of this rubbed over the glass, and then polished will ensure any card stripping, as it leaves a thin film of resin and resin on the glass. It takes, however, rather longer than the others, as the turpentine must evaporate.

**NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

### SUMMARY.

The Photographic Convention.—In connection with the meetings at Southampton next week we include in this issue portraits of those programmed to take part in the proceedings.

An article by Mr. E. W. Foxlee deals with the new ("ozobrome") process of Mr. Manly, in which a bromide is made the stepping-stone to a carbon print. The carbons are obtained from the bromide without exposure to light. The process is to be demonstrated at a Convention Conversazione. (P. 524.)

Mr. Arthur Payne gives a full account of the methods employed by him in using pinachrome-bathed plates for short-exposure photography of theatrical performances. (P. 529.)

We give a formula for a preparation similar to the "etchographates" mentioned last week. (P. 522.)

Cases of fogging from dark-slides with aluminium shutters point the precaution to avoid abrasion of the metal surface. (P. 522.)

The cinematograph is said to be in course of general application in America for popularising the work of the Department of Agriculture. (P. 522.)

Dr. Murray, in his "New English Dictionary," has included 10 "photo" words. (P. 523.)

The attitude of the P.P.A. to assistants' certificates calls forth verbal letters discussing the grounds on which assistants are said to have held aloof from the past and present scheme. (P. 527.)

A correspondent calls attention to the discrepancy in the charges made for photographing in show places to "amateur" (?) and professional photographers. (P. 539.)

A correspondent gives the remedy which he has found effective against catarrh as a result of handling platinum paper. (P. 538.)

Dr. Doelter, of Graz, writes in explanation of his method of making photo-micrographs of molten minerals. (P. 527.)

EX CATHEDRA.

## The Eve of the Convention.

**The Eve of the Convention.** The latest announcements to be made in regard to next week's programme at Southampton are that arrangements have been made for an informal talk on professional topics on Tuesday evening, from 7 to 8, in the secretaries' room. Our correspondence columns this week may provide more than one subject to be brought before this friendly conference of professional photographers attending the Convention. It is to be hoped that this feature of the Convention will be still more in evidence at future meetings. "Ozobrome" (see this week's article) will be demonstrated by Mr. Manly, and examples of Dr. Smith's printing out colour paper are also to be seen on exhibition during the week. Altogether we think the Convention Executive may congratulate itself on being able to make a very strong and representative show of the latest progress in technical photography.

\* \* \*

**Ozobrome.** Mr. Manly's new process, of which the specification was published in our last week's issue, is the subject of some notes in this issue by Mr. E. W. Foxlee whose claim to write on carbon printing and its cognate branches will scarcely be questioned. Mr. Foxlee's article and the extract from a circular of the Ozotype Company will make clear the two ways of "Ozobrome," and our readers should be able to judge for themselves the facilities which the new process puts in the way of those who make carbon prints and enlargements for pleasure or profit. "Ozobrome," we are glad to be able to announce, will be demonstrated by Mr. Manly himself at the Convention-Conversazione at Southampton on Monday evening next.

\* \* \*

**A Society Activity.**

**A Society Activity.** From a Society fixture card:—"The Society subscribes to the chief current photographic publications, and copies for several years past of the 'British Journal of Photography,' 'Amateur Photographer,' 'The Studio,' 'The Photogram,' and other works are preserved for reference." Such a duty, which we have no doubt is discharged by many societies, may be impressed upon others, who must plead guilty to sins of omission, as one which costs very little but is often worth a good deal to the society. Our recollection of several societies is that on occasions when some quoted authority or article was disputed, and reference was made to the file of the periodical in which it was to be found—the discussion invariably assumed an interest which it lacked at other times, when the opportunity for criticism was less definite and ranged over a narrower field. On "open nights," often the most profitable a society can arrange, we have seen the same thing occur, a reference to

a back number of one of the photographic journals provoking an active discussion, and often providing the members with subjects for another evening. A society should certainly preserve its journals for the private use of members, but the usefulness of this portion of its library is all the greater if the volumes are quickly accessible during the meetings.

\* \* \*

### **The Cinematograph in Agriculture.**

If we are to credit reports in the press, very extensive use is to be made of cinematograph pictures by the Department of Agriculture in the United States. The Department on its experimental stations has done a great deal of work on plant breeding, and has accumulated much information in the interest of the farming community. It is now proposed to increase the interest in scientific agriculture by touring the country with lectures, in which, by means of the cinematograph, a very forcible impression can be conveyed of the facilities which the Government holds at disposal. To this end films have been prepared which record on the screen in a few seconds the growth of plants or agricultural operations which occupied months in actual execution. The hourly exposures of the film which are made for this purpose are given automatically in a greenhouse lighted by arcs for exposure throughout the nights. It is anticipated that the pictures, thus obtained with infinite labour, will contribute in no small degree to the adoption of modern methods by the farmers.

\* \* \*

### **Aluminium as a Fogging Agent.**

A contemporary recently published a print sent by a correspondent showing uneven fogging action over almost the whole of the plate, and this was accompanied by a second print showing similar fog on an unexposed plate contained in the same slide. Only one slide of a set fitted with aluminium shutters showed the effect, hence, at first sight, it may not appear probable that the aluminium was responsible. Since attention was drawn to this case we have, however, heard of another. In this instance the plate showed parallel thin lines throughout its length. These occurred only in one slide, and, as the result of careful investigation, it was found that these lines corresponded with similar lines scratched on the inner face of the aluminium shutter. Further search revealed the fact that these scratches were caused by turned up rough edges of metal at the end of the slide, so that every time the shutter was pushed in the lines were re-scratched and fresh metal was exposed. It therefore appears that some emanation from the fresh metal surface attacked the plate. As the effect in each of these cases was confined to one slide, it does not appear that aluminium generally is to be condemned as "radio-active"; but the second case shows clearly that such slides should be made carefully, and that anything likely to abrade the surface of the aluminium should be carefully avoided.

\* \* \*

### **Etchograph Plates.**

The note on the above in our last issue has brought us several letters on the subject from readers who are anxious to try their hand at this class of work, and as one correspondent points out, whilst utterly unable to make an original drawing, he would have no difficulty in tracing from a print. There is, of course, the old method of drawing in waterproof ink over the outlines of a bromide or other silver print, and then dissolving out the silver image, but this obviously does not give a negative that can be duplicated. Somewhat

similar plates, or rather plates for a similar purpose, obtainable from Klimsch and Co. These are yellow white in colour, and after the drawing has been made are exposed to the fumes of ammonia, which blacken them. To make black etching plates the simplest thing to use is, of course, the etching ground as used by ordinary etcher for his metal plates. A good substitute will be found in ordinary Brunswick black diluted with a mixture of chloroform and benzole to a suitable consistency, and then flowed over the glass. For those who wish to make such plates the following method lately given in "Photographische Kunst" will be useful. The ground is 50 parts of Syrian asphalt powder, 10 parts of Venice turpentine, 10 parts of linseed oil varnish, and 10 parts of turpentine. These must be ultimately mixed and heated till the asphalt dissolves, and then more turpentine added till it is of a fluid consistency. This liquid should be poured over warmed glass, and allowed to set thoroughly hard and dry. This plate must now be dabbed all over with solution of gum-arabic, and then rinsed with water, and finally lamp-black mixed with a little glycerine water continually dabbed over the plate, till on looking through it it appears uniformly black. The print to be converted into line is now laid on the plate, and the lines traced with a hard pencil, pen, or other point. The turpentine removes the lamp-black and leaves the semi-transparent brown ground clearly visible in the lines, and etching then be performed in an ordinary retouching desk, or on any support with a mirror or other arrangement underneath to reflect the light through. Ordinary etching needles will of course answer perfectly.

## THE CONVENTION.

THE meeting of the Photographic Convention of the United Kingdom, next week is, as has already been pointed out, the twenty-first, and one may naturally take a glance over the past. In the infancy of the Convention there is no question that the meetings bore a totally different character from those of recent years; but then photography itself has changed during the last two decades. In the early days business meetings and a host of papers, some of great interest and value were read, and the social side was subordinated. But with the greater popularity of photography, and the greater dissemination of photographic literature the character of the meetings underwent an inevitable change. Possibly satiated with knowledge readily acquired, the members certainly paid more attention to the excursions and the social side, and less to the scientific. This is not to be wondered at. It is a change which has befallen nearly every other photographic society and body.

Complaints have been brought against the Convention and charges made that it was not fulfilling its purpose, but so long as the members were satisfied, outsiders had no right to complain. This year, apparently, with its coming of age the Convention has determined to prove that it intends to emphasize its position as a responsible and dignified body in the photographic world. Doubtless some of the members will still shirk the attendance at the evening meetings, and go in for lighter enjoyments, nor can they be blamed. Many make it part of their annual holiday, and look upon it as a pleasant reunion where such distinctions as amateur

professional are dropped, and all meet on the common ground of past friendship, and as members of the Photographic Convention of the United Kingdom.

In its infancy the Convention was not always in a flourishing condition financially, but for some years now it has gradually been accumulating funds, which we hope will be turned to good account. In this year's handbook, No. 47, we see announced that "The Council of the Photographic Convention of the United Kingdom, is prepared to make grants of money in aid of photographic research." The offer is not by any means a new one, as we have seen it was first made some seven or eight years ago, and in rules were framed and adopted, though but little has since been heard of the fact, nor has there been, so far as we can hear, any application made for some years.

We do not consider the rules perfect, but as any application would be considered on its merits by the Research Sub-Committee, they are no doubt elastic enough to permit of a fairly wide reading.

Now that the Convention has attained maturity, with a position to take itself a little more seriously, there are many subjects which it might well take up. It might form for England some of that work which is undertaken by the International Congress of Photography and so on. We advisedly use this term, because but little is known of the results of the latter body in England; nor do we think that the resolutions it adopts are generally applied in this country, and they are indeed open to very considerable criticism.

It may be advanced against these views that the Convention is not sufficiently authoritative to lay down laws and rules which shall bind photographers generally. Yet we think there is little doubt that carefully considered resolutions, adopted after consultation with those chiefly concerned, would carry considerable weight.

The programme for next week's meeting certainly promises well, and is a good earnest that in future the Convention will be still more useful than it has been in the past. There is at least, we are glad to say, no sign that it is losing that distinctive feature which makes it so contentedly supported by many of its oldest members, and attracts so many new friends, namely, a common ground of fraternisation and friendship, where many meet only once in the year. It is to be hoped, too, that the winter union which took place at the beginning of the year will become an annual fixture.

### "PHOTO" WORDS.

Photography wanted a testimonial of its capacity of being applied in all kinds of ways and to all sorts of purposes—the quality which a German editor may express by the one word "ausgestaltungsfähigkeit"—it can find it in the latest part of the "New English Dictionary,"\* which has now reached P in its alphabetical progress. For the compilers confess their surprise that

Vol. VII. (Ph. Piper), edited by Dr. James A. H. Murray. Oxford: The Clarendon Press. 5s.

the group of photo words occupies 15 columns and numbers in all 240. "Such an addition to the vocabulary," writes Dr. Murray, "has the discovery of one physical principle brought about." A fair number of these words, such as "photo-dynamics," "photo-thermic," have nothing to do with photography, expressing the relations of light only to other effects, and Dr. Murray distinguishes between the different uses of the same prefix, one of which denotes light, and the other photography or some photographic process. The latter list of words supplies our proof of the multifarious part played by the camera in the world's work and play. We have photo-ceramics and photo-etching, photo-sculpture and photo-spectroscopy, photo-theodolite and photo-telescope, photo-xylography (photographing on wood) and photo-chromy and photo-chronography, the words embracing the worlds of colour photography and the cinematograph. These examples are culled from a long list, where each represents a process or a whole branch of science owing its existence to the camera: the dictionary is, as we have said, a demonstration of how the photographic process travels along the highways of modern life and industry and penetrates also into its courts and alleys.

We hope that Dr. Murray's clear distinctions in regard to the double and treble work, which is done by certain "photo" words, may be borne in mind by writers at any rate. Thus we have "photo" as a colloquial abbreviation of "photograph," used both as a noun and a verb. The first is bad enough, and we have always set our faces against the degeneration of "photograph" into "photo," but "photoing" and "photo'd" are worse still. Carlyle is found guilty of the first, and Mr. Jerome K. Jerome of the second. Our feeling has been that while "photo" and its conjugated forms may be admissible in speech, they should be reserved for speech alone. "Photos," with its air of cheapness, is best left alone in correspondence, and we can hardly conceive that it is worth while to save words and ink by writing to a client:—"I find that my predecessor photoed you two years ago!"

Dr. Murray's list brings to light the obsolete words which we may perhaps have forgotten, though they were often used in the early days:—"photographist" for the photographer, and "photographees" for the sitters. "Photographize" was surely never used by anybody but Kingsley, from whom it is quoted; and "photogram," despite Mr. Snowden Ward's defence of it, gets a very lukewarm defence from Dr. Murray on etymological grounds, and is marked off "rare."

As to who coined the words "photography," "photograph," and "photographic," Dr. Murray attributes them to Sir John Herschel, by whom they were certainly used for the first known time on March 14, 1839. We have referred to this historical point in past issues, and have had to confess our failure to find the faintest documentary evidence of any use of the words before Herschel's paper on the date we have mentioned. Dr. Murray, it will be remembered, actively concerned himself in the search for a prior use of the words, and his researches, of which, naturally, only the results are embodied in the Dictionary, were sufficient to establish the English origin of the words.

### CONVENTION NOTES.

Hereford has been named as the place of meeting of the Convention in 1907.

We believe that Sir Benjamin Stone will be unable to be present the Tuesday evening, and that his place will be taken by Mr. C. Scamell, the secretary of the National Photographic Record Association.

The "British Journal" may be obtained in Southampton from W. Martin, 112, High Street; W. Bates and Co., 50, Oxford Street, and 147, Above Bar; and Randall and Son, 146, High Street.

Those who visited the exhibition of colour-photography at the "British Journal" offices will be interested in seeing the progress made by several exhibitors, whose work is to be shown by Mr. E. J. Wall at the evening meeting of July 13.

## A NEW CARBON PROCESS.

IN "Ex Cathedra" for June 1 there appeared a brief announcement that Mr. Thomas Manly, the inventor of the "Ozotype" process, had perfected a new method of producing carbon prints, possessing the very distinct claims to notice, namely, first, that prints are obtained indirectly by the exposure of bromide paper to light; in other words, from a bromide print

### ▲ Warnerke's Silver-Pigment Process.

As would be gathered from the previous note the new process is associated with the bromide paper process; an idea, let us say at once, which is by no means a new one. A quarter of a century ago the late Mr. Leon Warnerke discovered that a gelatinous bromide of silver film, developed with pyrogallol and

*Photograph by*

The President of the Photographic Convention of the United Kingdom.

*[the Platinotype Co.]*

or enlargement; and, secondly, that the carbon copies are obtained without exposure to light. Since then, the patent specification of this process, "Ozobrome," as Mr. Manly proposes to call it, has appeared, and the process is thus open for discussion.

Carbon printing, as everybody knows, was invented by Sir J. W. Swan, and published by him in 1864, and it is a little strange, considering the great advance made in the various processes of photography since that time, that the carbon process remains the same and is worked in practically the same way as it was forty years ago. One of the great obstacles to the more universal use of this process is that a double transfer of the picture is necessary, if it is to show the "right way about"—that is as regards right and left. But such is, of course, necessary, unless a laterally reversed negative is used in the printing. Also daylight is absolutely necessary for the exposure of carbon print. Both of these drawbacks are obviated in the new process.

became analogous in character to a carbon one that had been exposed to light—that is the parts acted upon by light had been rendered insoluble in warm water. This formed the subject of a patent, No. 1436, which he obtained in 1881. One of the methods described in the specification is to mix a pigment with the bromide emulsion, spread it on paper, and dry. The exposure under a negative and develop in the usual way for bromides. This done, a piece of single transfer paper is squeezed upon it and then the picture is developed in warm water, as if it were an ordinary carbon print. In this way a carbon picture is obtained on a silver image. The latter could then be got rid of by solution in perchloride of iron, leaving only the carbon one behind. In this way a carbon picture is obtained with only the exposure to light required for a bromide. Warnerke's process has been re-invented more than once, in a modified form, and, within the last couple of years in Germany. The modification in this instance was the immersing of the transfer paper in a solution of the bichromate of potash before

ing it to the bromide picture. Nothing practical, however, some of these processes, and that can readily be understood when the difficulty is considered of developing a bromide to the right depth on a dark surface like carbon tissue.

### The Two Methods of "Ozobrome" Printing.

Mr. Manly's new process, which he has patented, is quite different from the above, and is based upon an entirely different principle. In this process a bromide picture, which may be printed from the negative or an enlargement, is produced in the ordinary way by artificial light. After it has been developed, fixed and washed, it is put into a five per cent. solution of formalin for five minutes to harden the film and render it insoluble in warm water. It is then washed to free it from the formalin. It may then be used at once, or it may be dried and used at any future time. Bromide prints already in existence, if treated with the formalin, may be utilised. The procedure is:—If the picture has been dried it is immersed in cold water and a piece of the pigment plaster—the inventor says the ozotype plaster alone is suitable—is taken and the print is immersed till limp in the patent "pigmenting solution." The plaster is then squeezed together and allowed to rest for an hour or so. The "pigmenting solution" is, according to the specification, of potass bichromate with a mixture of potassium ferricyanide and potassium bromide, to which may be added a small quantity of alum. The print and plaster having remained in contact for the necessary time, there are then two methods of procedure open to us. The first is as follows:—The print, with its adherent plaster, is put into warm water at a temperature of 100 deg. to 110 deg. Fahr. After a short time the pigment will be seen exuding from the edges, when the plaster can be stripped off and the unaltered gelatine washed off, just as in the ordinary carbon process. Here we get a reversed carbon picture on the top of the silver one, the colour of which has been changed from a black to a yellowish-brown by the action of the carbon sensitising solution. The original image, if desired, can then be got rid of by dissolving away with the usual ferricyanide and hypo reducer, or with a solution of perchloride of iron, as suggested by Warnerke. The second method of working, which seems to me to be far more commercially valuable than the first, is slightly more complicated, but possesses very decided advantages. Instead of printing the picture with its adherent plaster direct in warm water it is put into cold water, the plaster stripped off, and at once squeezed on to a piece of single transfer paper. It is then pressed between blotting paper and allowed to rest for ten minutes or so, as in the usual method of working the carbon process by single transfer. It is then developed in warm water in the usual way. Here, again, we get a carbon picture which is not reversed as regards right and left, but without a silver image beneath it. The bromide original, which has been changed from black to a yellowish-brown, is washed to free it from chemicals, and can then be re-developed with any of the ordinary developers for bromide papers, and the print then comes equal in appearance to an original bromide. What more, it can be used again to produce other carbon pictures. Mr. Manly tells us that the same bromide original can continue to serve so long as the paper foundation will hold together.

As to the theory of his process, the inventor states in the patent specification:—"In the process forming the subject of the invention the ferricyanide and haloid salts first bleach or disorganise the silver image, and the reducing action, thereby set up, is taken advantage of to decompose the bichromate salt rendering the gelatine insoluble. The bichromate salt has, therefore, only a secondary action, and is not affected by the silver image. This is shown by the number of prints that can be produced from a single bromide silver print."

### A Cheap and Quick Route to Carbon Enlargements

No doubt many will be curious as to the quality of the carbon pictures produced by this method. All I can say, from my own experiments, is that they are just ordinary carbon pictures, from which they cannot be distinguished. With a good bromide original, the carbon prints I have made have been quite as good as if they had been printed in carbon from the negative itself. If this new process fulfils the expectations of its inventor, and from my limited experiments I see no reason why it should not, it will prove a great acquisition to workers of carbon. Almost everyone is now familiar with the making of direct prints and enlargements on bromide paper by artificial light, and when once a bromide picture is obtained many carbon ones may be made from it without the action of light. In the production of carbon enlargements the process should prove of great value. In the method at present followed a transparency has first to be made from the negative, and from that an enlarged negative. These two operations involve considerable time and there is a certain loss of quality entailed. When the enlarged negative is obtained the prints have to be made from it, which in winter is a long operation, particularly if a number are required. By the new method the bromide, contact print, or enlargement, is made direct from the original negative, and, once obtained, a good number of carbon prints may be made from it without the aid of light.

### Working Instructions for the "Ozobrome" Process.

The following are the instructions issued in a preliminary circular of the "Ozobrome" process, from which, with the inventor's permission, we quote:—

Materials Required.—A Bromide print, a piece of pigment plaster, and patent pigmenting solution. Both bromide and gaslight prints.

are suitable. Ozotype pigment plasters are alone suitable. Every trace of hypo must have been thoroughly removed from the bromide print.

Take the pigment plaster and immerse it in the pigment solution, removing any air-bells. As soon as the pigment plaster becomes limp or saturated, transfer it to the dish of water,

after hardening. Pour the working pigmenting solution into a porcelain dish somewhat larger than the bromide print, and place another dish containing cold water alongside of it. Take the bromide print and immerse it in the dish of cold water, face upwards, and remove any air-bells.

upon some flat, hard surface, such as glass or zinc. (It is advised that the thinner of the two papers should be uppermost when squeegeeing.) Then either hang the adhering papers up, or place them upon blotting paper till ready for development.

N.B.—The operation of bringing the saturated plaster into contact

t with the print under the water should be done as quickly as possible (say four or five seconds), otherwise some of the pigmentation contained in the gelatine film will be lost by diffusion in water.

The water should be changed after each print has been manipulated. Leave the bromide print with its adhering plaster for about an hour or 40 minutes. At the expiration of the specified time there are two methods which can be adopted to produce pigmented pictures.

#### Ozotype-Ozobrome.

Method I.—This is the non-transfer or ozotype method of pigmentation in which the bromide print itself is made to form the support of the picture, and is recommended for artistic work on the various grades of rough bromide paper on the market. The results by this method may be more easily worked upon with a brush than those by Method II.

Manipulation for Method I.—Immerse the adhering papers in hot water at about 105deg. or 110deg. F. Feel at the corners whether the papers are likely to separate easily. If so, remove the paper backing of the pigment plaster with a steady, unbroken pull, leaving the print in the water and throwing away the plaster backing. After a minute or two place the print upon a sheet of zinc and move all the soluble gelatine by moving the print up and down in the warm water, finishing the development by pouring the hot water upon the print with a small mug. Then wash the print in cold water for a few minutes.

Should any of the black silver deposit remain under the gelatine in the very deep shadows, it may be easily removed by the Howard Farmer reducer, after which wash for 15 minutes.

#### Carbon-Ozobrome.

Method II.—This is the transfer or carbon process in which the image, impressed upon the plaster by contact with the bromide print, is transferred to another support, leaving the original bromide print available for further transfers.

Manipulation for Method II.—Instead of placing the adhering papers in hot water, they are plunged into cold water, and after about one minute's soaking the papers can be easily separated by a steady pull from a corner. In this case the pigmented gelatine of the plaster will adhere to its own support, leaving the bromide

print uncovered and changed from black to a light brown colour. As the bromide print may be re-developed and used again, it is well

to place it in a separate dish of cold water at once, preparatory to washing.

The plaster now represents the exposed tissue in ordinary carbon printing, with the immense advantage that the image is reversed as regards right and left, thus securing an unreversed picture by single transfer.

Keep the plaster in the cold water face downwards, and slide a

piece of single transfer paper, gelatine surface upwards, underneath it.

After about 30 seconds, bring the underlying transfer paper into contact with the pigment plaster, and lift the two papers clinging together out of the water, place them on a sheet of zinc or glass, and squeegee them into contact, exactly as in carbon printing. Place between blotting-paper under slight pressure, and after 15 or 20 minutes develop as in Method I.

After separation from the pigment plaster, wash the print in water for half an hour, when it will be ready for re-development. Place the thoroughly washed print in a porcelain dish and pour over it a bromide developing solution such as amidol, hydroquinone, etc., then again wash thoroughly for half an hour. The bromide print is now restored to its original condition and efficiency, and can be used again for transfer printing. In fact, with care, many carbon prints can be made from one bromide print as long as the strength and substance of the original bromide paper will allow.

from a brief circular, is to produce portraits which possess character and feeling even though the process involve the subordination of the "photographic" quality of the result. The method adopted to this end includes the use of a screen during the making of the exposure and the printing from the negative; the critical definition of the lens being more or less broken down at these two stages. A considerable amount of brush work may be also done on the finished prints, which are offered to the sitter in sepia on heavy white paper (no mount), and possess, in the case of several examples shown to us, a soft and delicate character, which makes it easy for attention to centre on the face. Simplicity of background and accessories is carried to the extreme in Mattype portraits but the likenesses lose nothing, but gain a good deal, from this wholesome avoidance of a prevailing defect.

THE "Magazine of Fine Arts" has arranged two competitions for photographs illustrating passages of poetry—the first, two stanzas of Tennyson's "Brook," and the second, Mrs. Browning's—

"The new sight, the new wondrous sight!  
The waters round me, turbulent,  
The skies impassive o'er me."

THE death of Mr. Chalkley Gould, of the firm of Messrs. Debenham and Gould, art photographers, of Bournemouth and Southampton, took place last week at Llandudno, where Mr. Gould had been staying for the benefit of his health. He had been in delicate health for a long period, and a few weeks ago he had an attack of pleurisy. His death will be sincerely mourned not only by his wife and family of four sons and one daughter, but by a wider circle of friends.

## THE CAMERA AND THE PLAY,

Miss Zera Verdi and Chorus in "My Irish Molly O."

DAY the ubiquitous camera rules the world. People are pre-  
paring pictures to literature. Practically it is a set-back to those  
historic days when all thought was transmitted by pictorial  
representation, but actually it is a concession to the modern demon  
"haste," for more information may be gleaned from the perusal  
of a picture, and especially a photograph, than from a study of  
much descriptive literature, and, what is to the point, the know-  
ledge is obtained in much less time. The suggestion of novel sub-  
jects, and a description of the methods employed to obtain pictures

graphs with an exposure of less than one second with artificial light.  
The experiments have been conducted at various times, and under  
varied conditions, and successful results have been obtained with  
exposures varying from one-sixtieth of a second in the studio, one-  
tenth of a second in the street, and one-tenth to one-half a second  
in the theatre. Some of the writer's methods of using the camera  
in the theatre during the performance were published in the "British  
Journal Almanac," 1906, under the title of "The Camera at the

Figure under two focussed Arcs—Miss Jennie Albert (Sisters Albert).

under unusual circumstances, is naturally of interest to the photo-  
grapher who caters for the public taste, whether he is interested in  
studio, commercial, or Press work, and the publication of such  
information requires no apology.

During the last two or three years the writer has given some  
attention to a study of the conditions necessary to obtain photo-

Limelight Study—Miss Rose Harvey.

Play," and out of this article arose a private correspondence with  
two or three interested photographers who are working on similar  
lines. They desired further particulars, as it seemed the informa-  
tion in the article was too meagre to enable them to repeat the  
results, which were obtained at a speed to which they had not  
attained.

Miss Phyllis Dare singing "My Little Wooden Hut."

### Press Photography of the Drama.

In this article the explanation of the writer's methods has been elaborated, and additional matter is included about various points which it was thought would be self-evident, but seemingly require elucidation. The conditions are those which apply at the theatre or music-hall, when the photograph is taken during the performance, using the ordinary stage lighting only, and when the exposure must necessarily be of the nature of a snap-shot. The commercial value of this class of theatrical photography is greater than is at first apparent. The Press photographer will be able to visit the theatre on the first presentation of a new play, and obtain photographs which may be published with the essays of the dramatic critics. Photographs of popular actresses and actors may also be obtained whilst they are on the stage, when the presence of the audience, and the excitement of the performance, gives them the nervous energy which it is hopeless to expect in the studio. The postcard publisher will obtain a new class of subject, and may flood the towns with pictures of the popular scenes of the local pantomimes, or successful plays; whilst the commercial photographer will be able to supply the theatrical managers with prints of their productions, both as records, and for advertising purposes, at a minimum of expense, and absolutely no trouble or inconvenience, to the theatrical company—in fact, they need not know anything about the transaction.

### Theatre Tactics.

It will be found that, within reason, the acting managers of the various places of amusement will give the photographer every facility, for the strong light of publicity is the life and soul of their business, provided that he is assured that the work is not of a frivolous nature, for it is not to be expected that any manager will permit his "house" being turned into a photographic playground.

It is advisable to obtain permission to photograph from the acting manager in the first place, and then, having obtained it, to obliterate yourself, and especially the camera, to the utmost extent. As an

experiment, the writer has, however, on several occasions, photographed from the pit of a theatre, with a hand camera, without obtaining the necessary permission, though the nervous excitement engendered by the thoughts of what might happen is conducive to good photography. Fortunately, nothing happened, though the writer was observed using the camera by the attendant.

The theatrical management look most favourably upon the hand camera, as it does not attract attention, nor cause any inconvenience, either to their patrons or their staff, all of whom strongly object to the cumbersome stand-camera with the attached tripod stand, which is so awkward in a narrow gangway, and in the seclusion and darkness of the theatre is such a nuisance, both to the operator and to the audience.

### The Stand Camera in the Theatre.

The stand-camera may occasionally be used for obtaining large sized photographs of spectacular displays upon the stage, and especially when the work is undertaken at a rehearsal, or special "call" for the photograph; but as a rule it will be found that a hand-camera is requisitioned for the theatre. The type of hand-camera may be varied to suit the personal requirements of the operator, and it is immaterial whether it is of the twin lens type, the reflex pattern, or the ordinary box form of camera, as long as it is a workmanlike instrument, thoroughly well built, and of the highest class. It is absolutely necessary that it be fitted with a first-class lens of extreme rapidity, in order to utilise the whole of the available light, and so that a good, sharp negative may be obtained, which will bear enlarging up to three or four diameters for the average size of the pictures will be small—less than a quarter plate in size. The illustrations which accompany this article were taken with a hand camera fitted with a Zeiss Planar lens working at  $f/3.6$ . This lens gives a flat field covering the whole of the plate.

Miss Laura Love in "My Irish Molly O."

at  $f/3.6$ , which is the largest aperture which may, in the writer's opinion, be safely used for this work, on account of the desirability of reserving a little depth of focus, which will be found to be of great value when focussing upon a moving object, or for obtaining two or more planes in the picture of equal definition. For these reasons it would be found to be necessary to stop down the lens to  $f/3.5$ , even if it were capable of working at a larger aperture.

### Focal-Plane Exposures.

On account of the necessity for utilising the whole of the available light, the type of shutter fitted to the camera must be one which allows the whole of the light passed by the lens to act upon the plate, and is, therefore, of the highest efficiency; probably the focal-plane shutter will be used, and it ought to be arranged so that it may be used for fairly long exposures, such as a quarter of a second upwards. The slit in the focal-plane shutter is usually made to open, at its fullest extent, to a width of about one and a half inches, but it is advisable for use in the theatre to have the opening in the shutter cloth made to be of the full width of the plate in use—that is to say, the slit for a quarter-plate ought to be 3 in. wide, for a five by four plate 4 in. wide, and for a half-plate  $\frac{1}{2}$  in. wide; by these means it is quite possible to use the focal-plane shutter for fairly long exposures. The writer has considered the plan of adapting the shutter to work with a time valve, fitted to the tube of a pneumatic release, so as to obtain exposures of two seconds to half a second, when such are required for a badly lit subject, but he has not yet had an opportunity of working with such an arrangement; it ought, however, to work equally as well on the focal-plane shutter as it does on the roller-blind shutter. It is advisable to make the exposure with a pneumatic release in preference to using a trigger, or pressing a button, both of which movements are liable to jerk the camera at the moment of exposure, unless the camera is steadied against some fixed support. This risk of movement may be avoided by placing the india rubber ball of the pneumatic release in the mouth and squeezing it by the teeth when the exposure is required; this method also allows the operator the use of both hands to control the camera.

### Focussing the Subject.
